**Figure S2 A-D: *In silico* predictions of PAARs on Polprim-complex.**

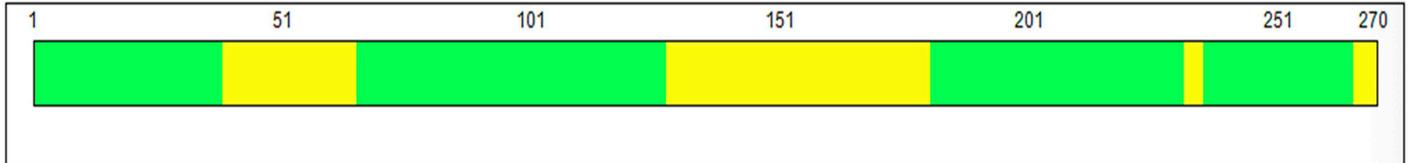

Graphical output of *in silico* PAAR predictions via Netphos v3.1: (A) POLA1 (p180, 1462 aa), (B) POLA2 (p68, 598 aa) (C) PRIM1 (p48, 420 aa), and (D) PRIM2 (p58, 509 aa) with 123, 81, 35 and 48 predicted phospho- S, T, Ys predicted in the four subunits respectively (More details can be found in Supplementary Table 3, sheet 5). X-axis is the number of aa residues. Y-axis is a measure of the phosphorylation potential on a scale of 0 to >1 with a cut off at  $\geq 0.5$  (magenta line) for positive predictions.

### Figure S3 A-C: PAARs on RPA-complex by MS analysis

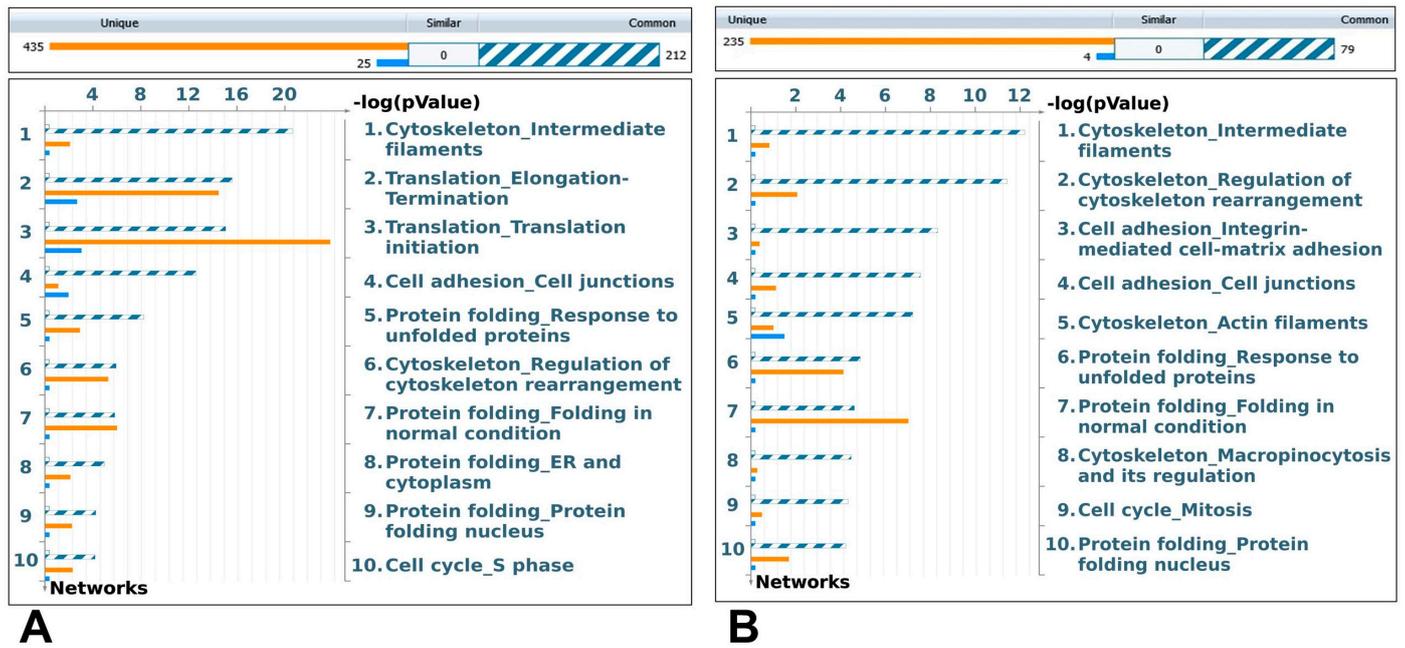

LC-MS/MS analysis of the IP eluates resulted in very similar sequence maps (with modifications) from both Cont. and ETO treatments in each of the three subunits of RPA-complex. Therefore, like SV40 LT and Polprim only one representative from each is demonstrated. Sequence coverage of detected tryptic peptides in the entire protein is 100% for all three subunits- (A) RPA1 (p70), (B) RPA2 (p32) and (C) RPA3 (p14). For further details of PAARs on RPA subunits see Table S5. The overall detection coverage (colored by confidence levels of peptide detection) by MS/MS analysis is shown by a scale bar graphic on top of the full sequence map. The identified tryptic peptides and phosphorylation (P) are colored by confidence of identification: green (high) yellow (medium) red (low) and white (undetected by MS/MS). The acetylation of free amine groups is on any aa including Lys (K) and Arg (R) termini and occur spontaneously during experimental steps and may not be biologically meaningful unless validated. To avoid overinterpretation of the data, we do not include acetylated residues in our findings. Abbreviations: P= phosphorylated residues, A= acetylated residues.

**A****B**

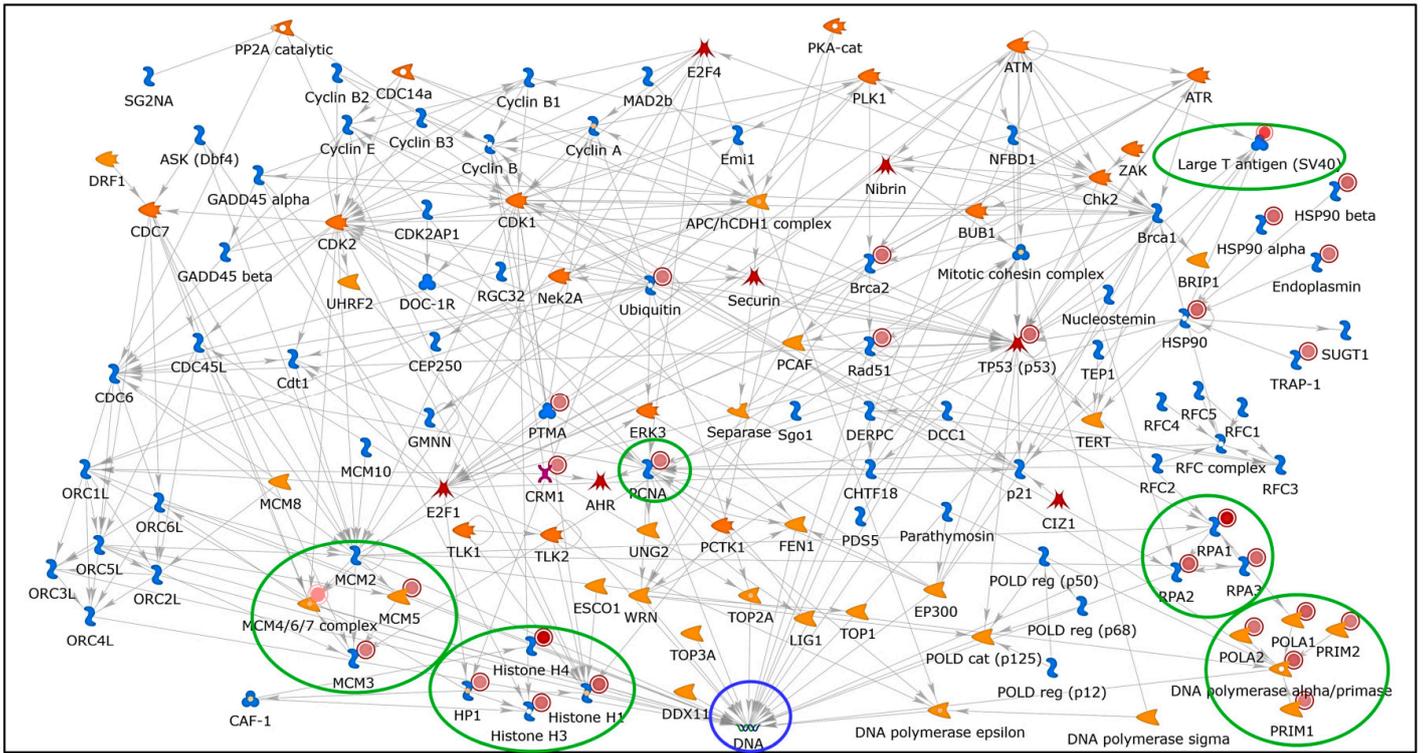

**Figure S4 A-C: *In silico* predictions of PAARs on RPA-complex.**

Graphical output of *in silico* predictions via Netphos v3.1 in: (A) RPA1 (p70, 616 aa), (B) RPA2 (p32, 270 aa) and (C) RPA3 (p14, 121 aa) with 70, 34 and 9 predicted phospho- S, T, and Ys on the three subunits, respectively. (See further details in Supplementary Table 5, sheet 4). X-axis is the number of aa residues. Y-axis is a measure of the phosphorylation potential on a scale of 0 to >1 with a cut off at  $\geq 0.5$  (magenta line) for positive predictions.

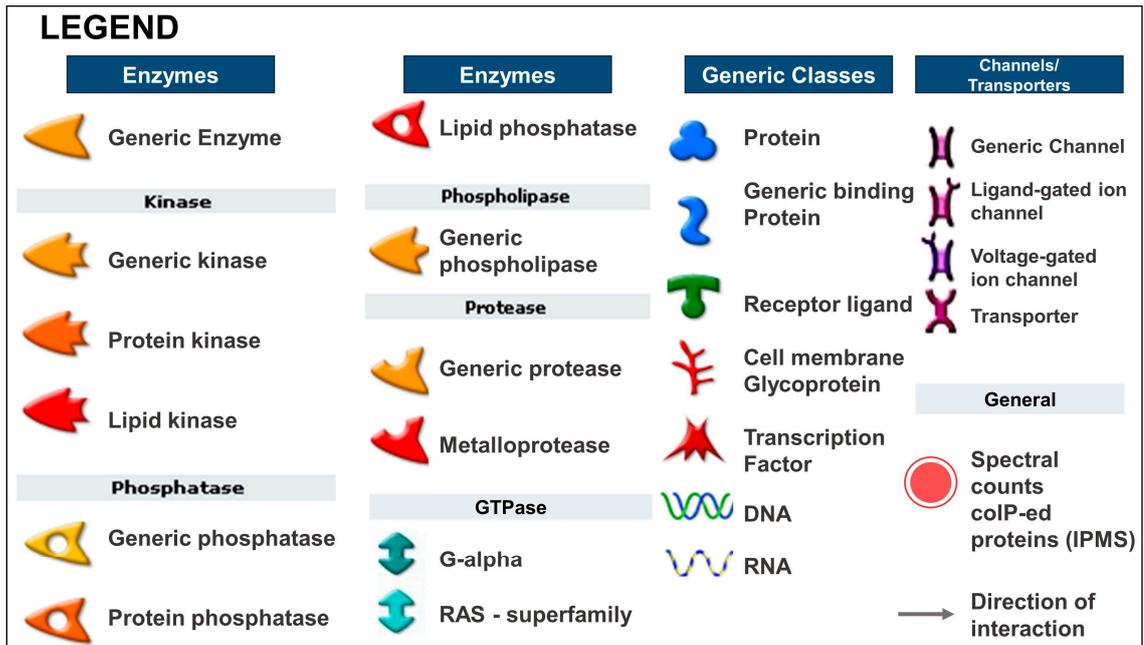

**Figure S5 A-B: GO Enrichment Analysis; Process Networks with Polprim and RPA associated proteins**

Gene content was aligned between the individual uploaded lists of associated proteins with Polprim and RPA within the web-based integrative software suite (MetaCore). The genes sorted into three categories as seen in the histograms: 1) common to both Cont and ETO (hatched blue and white), 2) unique to Cont (solid orange) and 3) unique to ETO (solid blue) in the top panels of: (A) Polprim-associated gene IDs split into 212 common, 435 and 25 objects unique to Control and ETO respectively and (B) RPA associated gene IDs sorted to 79 common, 235 and 4 unique NOs to Control and ETO respectively. The top 10 enriched process networks are arranged in negative log p-values from most to least relevant in the bottom panels of the GO enrichment analyses for protein lists from (A) Polprim-complex and (B) RPA-complex. Sorting is done for p-value of the “common” set of genes/NOs. “ See Table 7 -sheet 2-3 for underlying statistics. Translation related networks were the most enriched networks due to the coIP of several ribosomal proteins (RP) as integral components of the ribosome that interact with RNA and other cellular components with high affinity. RP aggregates are often found in IPs from lysates of robustly growing cells or in stress response.

## B

### Figure S6 A-B: Cell Cycle \_ S Phase related network and biological processes

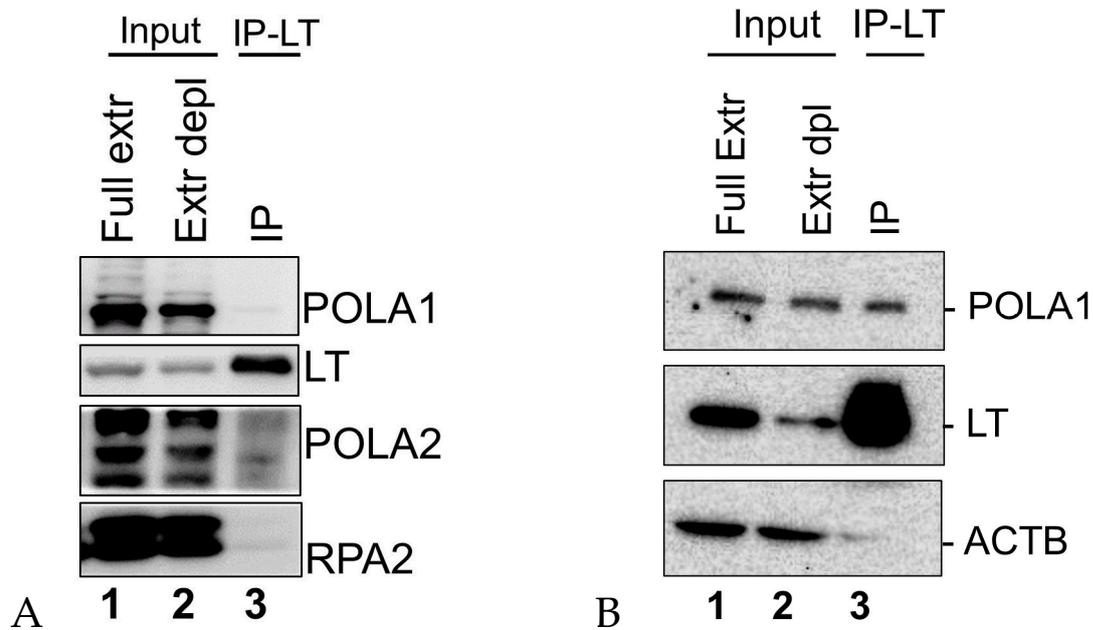

(A) Cell Cycle\_S Phase was the top overconnected network associated with the term “DNA replication” in the MetaCore database. The final merged network combines the prebuilt network in the database with our activated experimental dataset, along with the addition of SV40-LT (indicated using a generic protein descriptor). Twenty-six gene IDs from our IPMS dataset: LT, PCNA, MCM3, MCM4, MCM5, MCM7, TP53, Rad51, CRM1(XPO1), BRCA2, Ubiquitin, HSP90 family: HSP90 alpha (HSP90AA1), HSP90 beta (HSP90B1), PTMA, TRAP1 and members of the Histone family, subunits of the Polprim and RPA complexes, were included in this network (solid red circles). Several proteins (green ovals) within the network were also previously reported to be associated with the SV40 DNA replication fork (Table S8 sheet 3). Individual proteins or objects are represented as nodes and different shapes of the nodes represent functional classes of proteins and are clarified in the legend. (Statistics: Table S9, sheets 1-9). While the enrichments and networks building statistics are calculated according to our uploaded experimental dataset (gene IDs) without spectral counts (SC), the SC are used to set thresholds to allow visualization of the semi-quantitative measure for coIP-ed protein abundance in the IP eluates or cell lysate (solid red circles associated with network object). The network of interactions (also called edges: grey arrows) between proteins (with direction) were based on the curated knowledgebase within Metacore. The arrowheads indicate the direction of the interactions. Large T-antigen was the only SV40 specific protein added to every network analysis. It mapped to a generic protein in Metacore, to which the red solid circle was added, the color consistent with spectral counts in our MS results.

**(B)** The significant biological processes enriched within the network were related to DNA metabolic process, DNA replication, cell cycle, and DNA damage and repair, among others and included several genes from our results (Figure S7). Several proteins such as MCM3, MCM5, MCM4, MCM7 that are part of the mammalian replication machinery were found to coIP with SV40 LT and Polprim. This is not yet fully understood. Perhaps LT's association with Polprim and RPA results in larger replication complexes that is able to precipitate the MCMs. In summation, this network validates our IPMS protein dataset to be representative of both SV40 and human DNA replication in the cell cycle. The enrichments and network building statistics were calculated according to our experimental dataset (For statistics underlying the "Cell cycle\_ S phase" network see Table S9, sheets 1-9).

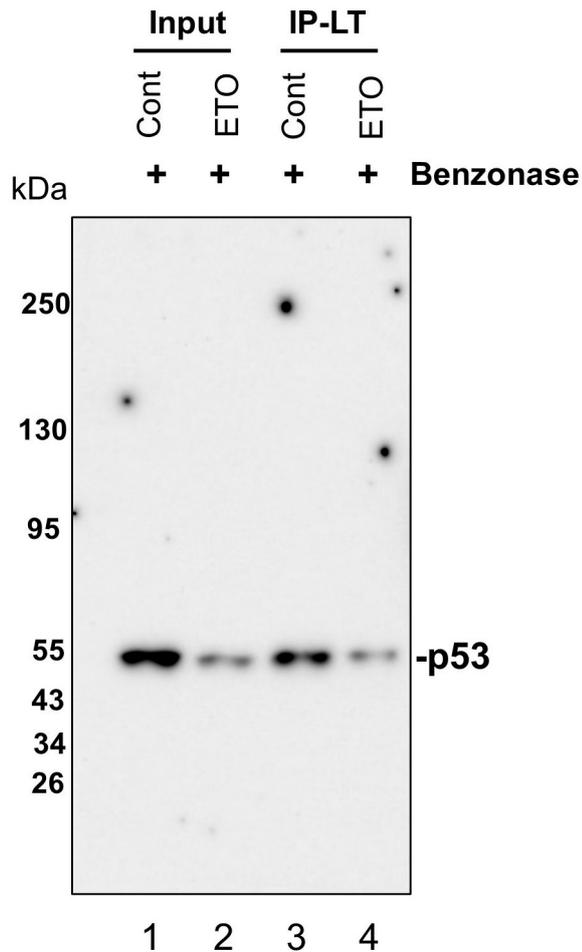

**Figure S7: PAARs on SV40 LT by MS analysis**

PAARs on SV40 LT amino acid sequence using MS/MS analysis. Only one representative sequence map with modifications for SV40 LT is shown since there was a large overlap between Cont and ETO. Sequence coverage of detected peptides (by MS) was 91% for both treatments. Tryptic peptide K67-K129 remained undetected by MS/MS (For further details of SV40 LT PAARs see Table S1). The tryptic peptide detection and S/T/Y phospho-sites (P) are highlighted with colors by confidence levels (scale bar graphic on top of the full sequence map): green (high) yellow (medium) red (low) and white (undetected by MS/MS). To avoid overinterpretation of the data the spontaneous O and A modifications of free amine groups are not included in this report (see Methods). Abbreviations: P= phosphorylated residues, A= acetylated residues.

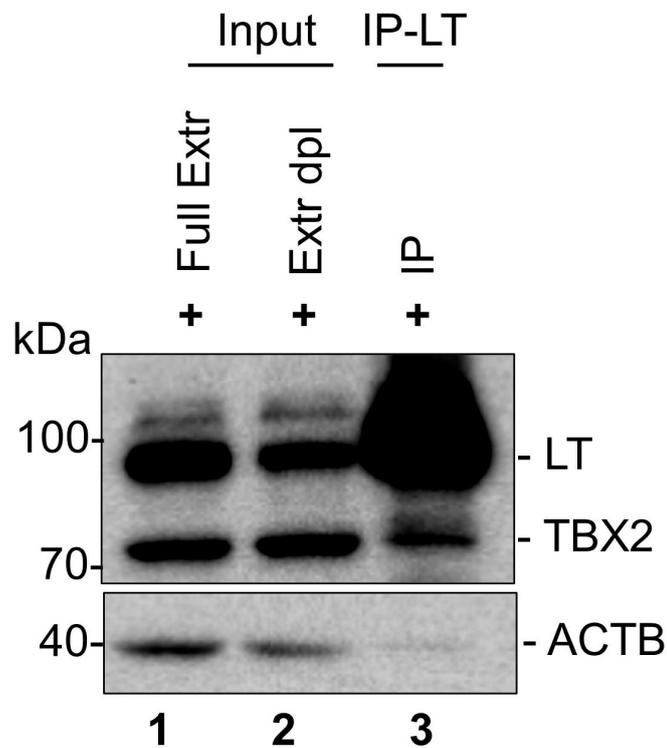

**Figure S8A-B : Co-immunoprecipitation of POLA1, POLA2, RPA2 with SV40 LT**

Two immunoprecipitation experiments were performed with HEK293T cell extract (Input), before binding (Full extr) and after binding (Extr depl) with SV40 LT-specific monoclonal antibody. A) Immunoblot of the Input (lanes 1, 2) and IP-LT (lane 3) showed POLA1, POLA2, and RPA2 co-IP with LT. B) Input (Lanes 1, 2) and IP-LT (Lane 3) showed POLA1, LT and ACTB

**Figure S9: Co-immunoprecipitation of p53 with SV40 LT after Benzonase treatment**

Immunoprecipitation experiments using SV40 LT-specific monoclonal antibodies were performed from whole cell extracts: untreated (Cont) and etoposide treated (ETO) HEK293T cells (Input). The cell extracts (input) were then treated with Benzonase nuclease (see method). Immunoblotting of the Input (lanes 1, 2) and IP-LT (lanes 3, 4) were probed with antibodies to p53/TP53. The tumor protein p53 (p53/TP53) co-IPs with LT even after Benzonase treatment. The coIP of p53/TP53 without Benzonase treatment was observed in Lane 11 of Fig 2A and Lanes 3, 4 in Figure 9 in the main paper.

**Figure S10: Co-immunoprecipitation of TBX2 (~ 72kDa) with SV40 LT after Benzonase treatment**

Immunoprecipitation experiments using SV40 LT-specific monoclonal antibodies were performed from whole cell extracts of HEK293T cells (Input). The cell extracts (input) were then treated with Benzonase nuclease (see method). Immunoblotting of Input (Full Extr: before binding to antibody and Extr dpl: after binding to antibody) (lanes 1, 2) and IP-LT (lanes 3) were probed with antibodies to SV40 LT and TBX2 (upper panel) and ACTB ( $\beta$ -actin lower panel). The TF, T-box transcription factor 2 (TBX2) (~72kDa) co-IPs with LT even after Benzonase treatment.
