Bioinspired and Photo-Clickable Thiol-Ene Bioinks for the Extrusion Bioprinting of Mechanically Tunable 3D Skin Models

Luís B. Bebiano ^{1,2}, Rafaela Presa ^{1,2,3}, Francisca Vieira ^{1,2}, Bianca N. Lourenço ^{1,2} and Rúben F. Pereira ^{1,2,3,*}

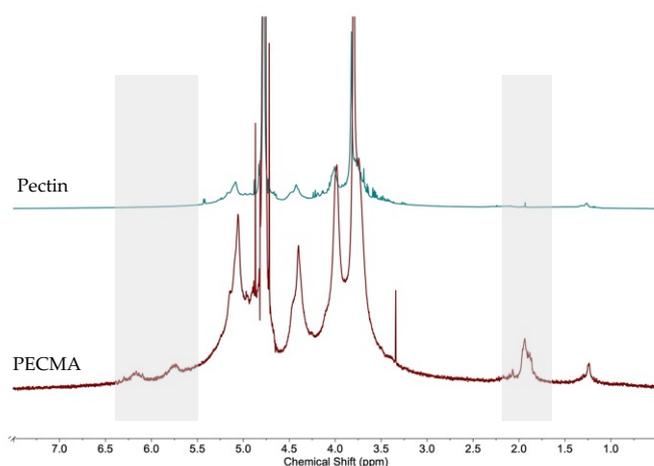

Figure S1. ¹H NMR spectra of pectin and pectin methacrylate (PECMA), showing two new peaks in PECMA (5.50–6.50 ppm) assigned to the methylene group in the vinyl bonds and a sharp peak at 1.90 ppm corresponding to the methyl group. Degree of methacrylation is ~20% and was calculated as detailed [5].

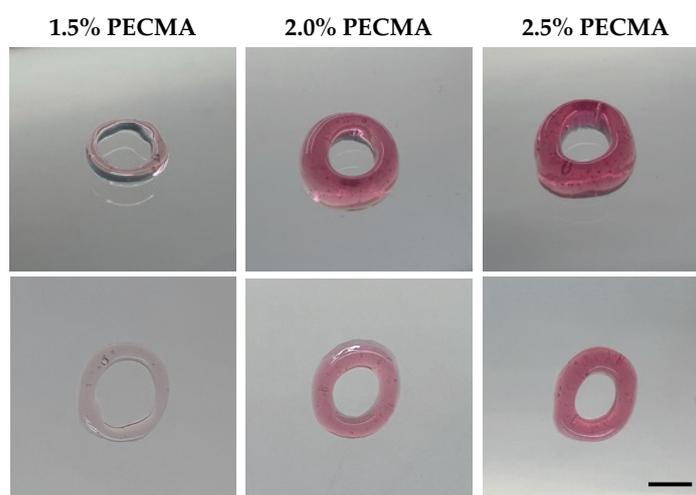

Figure S2. Representative images (top: isometric view; bottom: top view) of bioprinted hollow constructs ($\varnothing = 10$ mm) created using ionically crosslinked PECMA inks (6 mM CaCl_2). Inks were extrusion bioprinted into 10 layers constructs, sustaining the shape without photocrosslinking in a polymer concentration-dependent manner (scale bar: 5 mm).

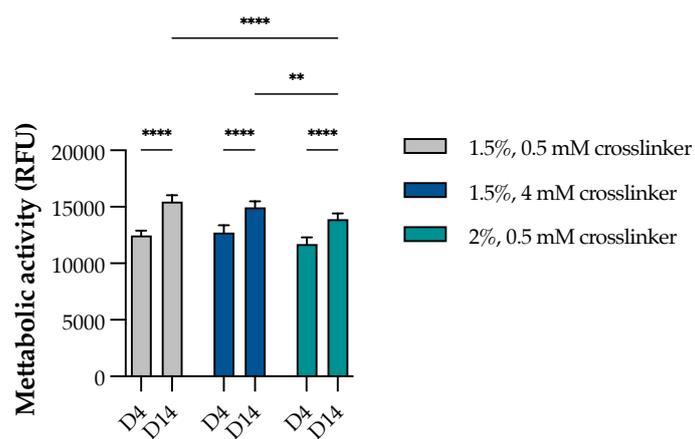

Figure S3. Metabolic activity of dermal fibroblasts within double crosslinked PECMA hydrogels (6 mM CaCl₂, 2 mM RGD) prepared with varying polymer contents (1.5% and 2%) and MMP-peptide crosslinker concentrations (0.5 mM and 4 mM) at days 4 and 14 of culture (** $p < 0.01$, **** $p < 0.0001$).
