Supplementary Figure S1. The time evolution of the electrostatic interactions within the broad m-gate network in MD simulations on wild-type (a) and mutant (b-f) AAC.

Supplementary Figure S2. The solvent within the pocket and bulk solvent at the matrix side is more separated due to presence of a tyrosine before the kink proline in domain 2 **(a)** and domain 3 **(b)**.

Supplementary Figure S3. The R30:R71:R151 stacking structure and time evolution of electrostatic interactions between the capping arginines and N-termini of odd-numbered helices. **(a)** A snapshot of *all4A*-AAC in which the the R30:R71:R151 stacking structure became dissociated and the cyclic electrostatic network between capping arginines (R30, R139 and R236) and N-termini of odd-numbered helices is disrupted. Yellow dash lines are added manually to indicate the H-bonds that do not appear in the shown snapshot. **(b)** A snapshot of *wild-type* AAC in which the the R30:R71:R151 stacking structure and the cyclic electrostatic network between capping arginines and N-termini of odd-numbered helices are maintained. The cyclic electrostatic interactions are shown in black dash lines, with occupancies shown in blue numbers. The occupancies were calculated over the 3- μ s trajectory. **(c)** Time evolutions of the distances between the three capping arginines and the corresponding N-termini of odd-numbered helices.
