

Supplementary Materials: A One-Pot Tandem Strategy in Catalytic Asymmetric Vinylogous Aldol Reaction of Homoallylic Alcohols

Xufeng Hou, Zhenzhong Jing, Xiangbin Bai and Zhiyong Jiang

1. General Information

1.1. General Procedures and Methods

Experiments involving moisture and/or air sensitive components were performed under a positive pressure of nitrogen in oven-dried glassware equipped with a rubber septum inlet. Dried solvents and liquid reagents were transferred by oven-dried syringes or hypodermic syringe cooled to ambient temperature in a desiccator. Reactions mixtures were stirred in 10 mL sample vial with Teflon-coated magnetic stirring bars unless otherwise stated. Moisture in non-volatile reagents/compounds was removed in high vacuo by means of an oil pump and subsequent purging with nitrogen. Solvents were removed in vacuo under ~30 mmHg and heated with a water bath at 30–35 °C using Changcheng rotary evaporator with Changcheng aspirator. The condenser was cooled with running water at 0 °C.

All experiments were monitored by analytical thin layer chromatography (TLC). TLC was performed on pre-coated plates, 60 F₂₅₄. After elution, plate was visualized under UV illumination at 254 nm for UV active material. Further visualization was achieved by staining KMnO₄, ceric molybdate, or anisaldehyde solution. For those using the aqueous stains, the TLC plates were heated on a hot plate.

Columns for flash chromatography (FC) contained silica gel 200–300 mesh. Columns were packed as slurry of silica gel in petroleum ether and equilibrated solution using the appropriate solvent system. The elution was assisted by applying pressure of about 2 atm with an air pump.

1.2. Instrumentations

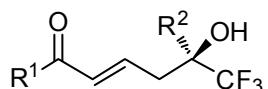

Proton nuclear magnetic resonance (¹H-NMR), carbon NMR (¹³C-NMR), and fluorous (¹⁹F-NMR) spectra were recorded in CDCl₃ otherwise stated. Chemical shifts are reported in parts per million (ppm), using the residual solvent signal as an internal standard: CDCl₃ (¹H-NMR: δ 7.26, singlet; ¹³C-NMR: δ 77.0, triplet). Multiplicities were given as: s (singlet), d (doublet), t (triplet), q (quartet), quintet, m (multiplets), dd (doublet of doublets), dt (doublet of triplets), and br (broad). Coupling constants (J) were recorded in Hertz (Hz). The number of proton atoms (n) for a given resonance was indicated by nH. The number of carbon atoms (n) for a given resonance was indicated by nC. HRMS was reported in units of mass of charge ratio (m/z). Mass samples were dissolved in CH₃CN (HPLC Grade) unless otherwise stated. Optical rotations were recorded on a polarimeter with a sodium lamp of wavelength 589 nm and reported as follows: [α]_λ^{T°C} (c = g/100 mL, solvent). Melting points were determined on a melting point apparatus.

Enantiomeric excesses were determined by chiral High Performance Liquid Chromatography (HPLC) analysis. UV detection was monitored at 254 nm, 230 nm and 210 nm at the same time. HPLC samples were dissolved in HPLC grade isopropanol (IPA) unless otherwise stated.

1.3. Materials

All commercial reagents were purchased with the highest purity grade. They were used without further purification unless specified. All solvents used, mainly petroleum ether (PE) and ethyl acetate (EtOAc) were distilled. Anhydrous DCM and CH₃CN were freshly distilled from CaH₂ and stored under N₂ atmosphere. THF, Et₂O, *tert*-butylbenzene and toluene were freshly distilled from sodium/benzophenone before use. Anhydrous methanol and ethanol were distilled from Mg. All compounds synthesized were stored in a -20 °C freezer and light-sensitive compounds were protected with aluminium foil.

2. Characterization of Adducts

3. Proposed Mechanism

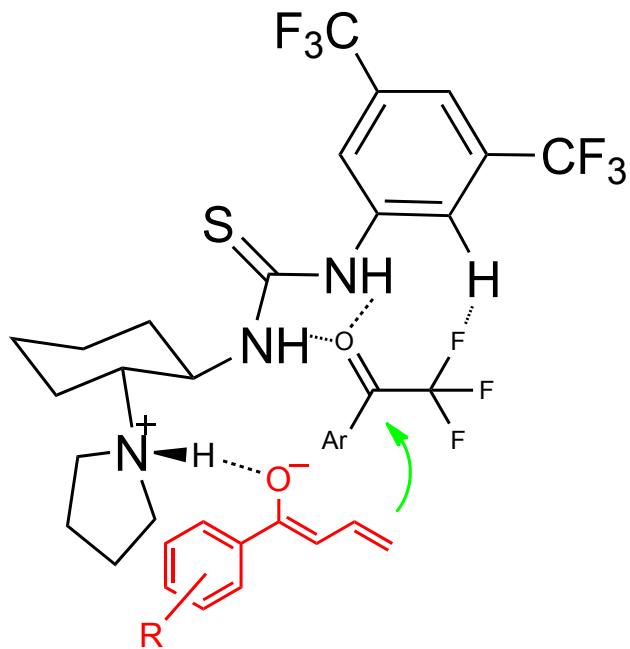

Figure S27. The proposed mechanism.

After abstraction of α -proton of allyl aryl ketones, the generated dienolates of allyl aryl ketones should bind to the R_4N^+ arm of the catalyst via electrostatic interaction. The thiourea group of the catalyst could simultaneously interact with trifluoromethyl ketones via two hydrogen bonds. A non-classic hydrogen bond between C–F bond of trifluoromethyl ketones and C–H bond of aryl substituent of thiourea leads to the most stable interaction. After nucleophilic addition, the vinylogous aldol adducts were obtained with the observed enantioselective results. The ortho-substituents on phenyl rings of allyl aryl ketones should increase the steric effect with pyrrole ring of the catalyst, leading to poor enantioselective results.
