Strain characterization

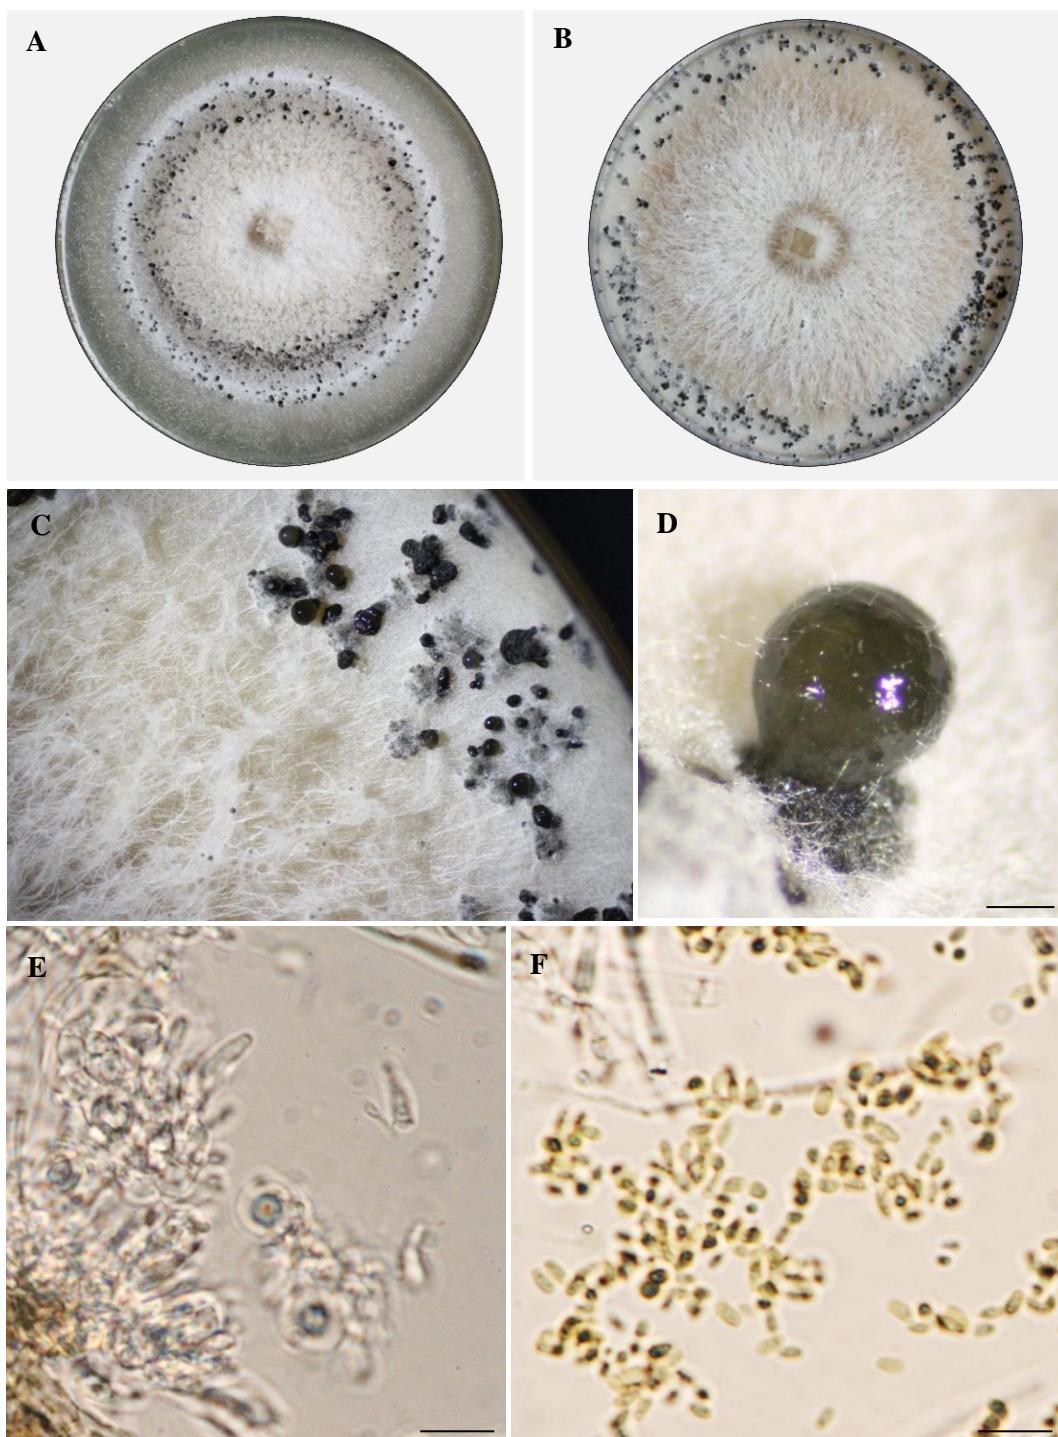

Figure S1. Morphological characteristics of *Dendrothyrium variisporum*. A culture on PDA after 21 days on 9 cm dish, B culture on OMA after 21 days on 9 cm dish , C Conidiomata forming on the edge of culture on OMA medium, D Conidiomata, E Conidiogenous cells, F conidia, scale bar E, F 10 μ m, D100 μ m.

Morphology and size of macroscopic features of the culture on the plate were determined. Colonies on PDA and OMA spread over the whole 9cm dish after 21 days. Colonies on PDA appear white in the center with an even colourless margin. On OMA, colonies with even couloress margin

and white dense aerial mycelium in the center are observed. Conidiomata eustromatic, formed on the edge of culture, often merged to complexes, dark brown to dark, reaching 300-500 μ m of diameter. The outer surface covered by glabrous hyphae. Conidia (1-2 μ m) \times (3-4 μ m), aseptate, variable in shape: subglobose, ellipsoid or ovoid, oliveaceous-brown. Conidiogenous cells (12-20) \times (2-3) μ m, acropleurogenous conidiophore [1].

After Local Alignment Search Tool (BLAST) search of the nucleotide sequence ITS from the National Center for Biotechnology Information database (<http://www.ncbi.nlm.nih.gov/>), the ITS rDNA sequence of the producer fungus exhibited 100% homology to *Dendrothyrium variisporum* CBS 121517.

Based on both morphological and molecular data, the producer strain could be identified as *Dendrothyrium variisporum*
