Synthesis and spectral characterization

{[*i*PrHNCH₂(*o*-C₆H₄N)]Pd[(C₇H₁₀)Me](NCMe)}(BF₄) (2a). To a stirred solution of **1a** (260 mg, 0.65 mmol) in a 5:1 THF/acetonitrile mixture (12 mL) was added 1.3 equiv. of norbornene (84 mg, 0.89 mmol) in THF (6 mL) slowly. The mixture was stirred at room temperature for 1h, and then filtered through Celite. After removal of solvent *in vacuo*, the residue was washed with hexane (10 mL) and filtered. The crude product was washed with hexane (2 × 5 mL) again and dried in *vacuo*. The desired air-sensitive complex was obtained as light yellow powder in 83% yield (222 mg, 0.54 mmol). ¹H NMR (CDCl₃, 400 MHz) for major **T-2a**: δ 8.32 (d, J_{H-H} = 5.3 Hz, 1H, Py H-6), 7.87 (td, J_{H-H} = 7.5, 1.4 Hz, 1H, Py H-4), 7.42 (m, 1H, Py H-3; 1H, Py H-5), 4.53 (dd, J_{H-H} = 16.6, 6.4 Hz, 1H, Py-CHH'N), 3.94 (m, 1H, NHCH(CH₃)₂; 1H, Py-CHH'N), 2.75 (sept, J_{H-H} = 6.5 Hz, 1H, NHCH(CH₃)₂), 2.39 (bs, 3H, NCCH₃), 2.32 (d, J_{H-H} = 7.3 Hz, 1H, Pd-CH-), 2.13 (bs, 1H, bridgehead CH), 1.89 (d, J_{H-H} = 3.0 Hz, 1H, bridgehead CH), 1.73 (quin, J_{H-H} = 7.4 Hz, 1H, CH₃-CH-), 1.63 (m, 1H, *syn* apical CHH'), 1.53 (m, 1H, *exo*-CHH'-), 1.46 (d, J_{H-H} = 7.2 Hz, 3H, CH₃-CH-), 1.26 (m, 1H, *exo*-CHH'-), 1.19, 1.09 (d, J_{H-H} = 6.3, 6.5 Hz, 6H, NHCH(CH₃)₂), 1.18–1.00 (m, 1H, *anti* apical CHH'; 2H, *endo*-CHH'); minor **T-2a**: δ 8.42 (d, J_{H-H} = 5.2 Hz, 1H, Py H-6), 7.88 (m, 1H, Py H-4), 7.42 (m, 1H, Py H-3; 1H, Py H-5), 4.47 (dd, J_{H-H} = 16.6, 6.3 Hz, 1H, Py-CHH'N), 3.94 (m, 1H, NHCH(CH₃)₂; 1H, Py-CHH'N), 2.75 (m, 1H, NHCH(CH₃)₂), 2.39 (bs, 3H, NCCH₃), 2.31 (m, 1H, Pd-CH-), 2.16 (bs, 1H, bridgehead CH), 1.82 (bs, 1H, bridgehead CH), 1.63 (m, 1H, *syn* apical CHH'), 1.53 (m, 1H, *exo*-CHH'-), 1.46 (m, 3H, CH₃-CH-), 1.35 (m, 1H, CH₃-CH-), 1.26 (m, 1H, *exo*-CHH'-), 1.13, 1.05 (d, J_{H-H} = 7.1, 7.2 Hz, 6H, NHCH(CH₃)₂), 1.18–1.00 (m, 1H, *anti* apical CHH'; 2H, *endo*-CHH'). ¹³C NMR (CDCl₃, 125.753 MHz) for major **T-2a**: δ 164.48 (Py C-2), 148.99 (Py C-6), 139.31 (Py C-4), 124.47 (Py C-5), 123.11 (Py C-3), 122.19 (NCCH₃), 53.77 (Py-CH₂N), 52.57 (Pd-CH-), 51.92 (NHCH(CH₃)₂), 45.22 (CH₃-CH-), 45.04, 44.78 (bridgehead CH), 34.60 (apical CH₂), 30.12, 29.32 (CH₂), 22.44, 21.34 (NHCH(CH₃)₂), 21.77 (CH₃-CH-), 3.29 (NCCH₃); minor **T-2a**: δ 164.25 (Py C-2), 146.90 (Py C-6), 139.51 (Py C-4), 123.98 (Py C-5), 123.48 (Py C-3), 122.06 (NCCH₃), 57.34 (Pd-CH-), 53.19 (Py-CH₂N), 51.39 (NHCH(CH₃)₂), 45.18 (CH₃-CH-), 45.61, 44.96 (bridgehead CH), 34.60 (apical CH₂), 30.28, 29.22 (CH₂), 22.75, 21.49 (NHCH(CH₃)₂), 21.12 (CH₃-CH-), 3.29 (NCCH₃). General procedure for copolymerization of ethylene-norbornene

Into a 600 mL Parr autoclave equipped with a magnetic stirring bar was placed norbornene (0.5–10 g) in dried CH_2Cl_2 (50 mL). The autoclave was sealed. Upon flush with ethylene gas several times, the ethylene gas was pressurized. The solution was stirred for 20 min in order to be saturated with ethylene gas. After release of ethylene pressure, the palladium complexes (0.06 mmol) were added, and then refilled with ethylene gas up to 21 bar. The mixture was stirred for 30 min, and the ethylene pressure was kept constant during the copolymerization runs. The reaction was quenched with venting the autoclave followed by adding 100 mL MeOH–HCl in 4:1 v/v ratio. The precipitated polymers were filtered from solution, washed with methanol and dried in vacuum oven at 80 °C overnight.

General procedures for the kinetic study determined by variable-temperature ^1H NMR spectroscopy

VT-NMR Insertion Kinetics for Ethylene

An NMR tube was charged with 0.7 mL of $[(\text{N}^{\wedge}\text{N})\text{Pd}(\text{Me})(\text{NCMe})]\text{BF}_4$] solution ($2.5 \times 10^{-2} \sim 1.1 \times 10^{-3}$ M) in CDCl_3 and tetramethylsilane (TMS) as internal standard under nitrogen atmosphere, and then frozen with dry ice/acetone bath. After evacuation, desired amount of ethylene (4–8 mL) was injected by gastight syringe. The tube was warmed briefly around the melting point of CDCl_3 and shaken vigorously in order to adequately dissolve the ethylene. The sample was placed in a precooled NMR probe at desired temperature, and the decrease in intensity of Pd-Me was measured by using ^1H NMR spectroscopy. Spectra were taken at intervals of 91–301 sec. The slope of the line defined by the $\ln(\text{integral of Pd-Me})$ signal vs time afforded the first-order rate constant, and the reaction was monitored for 2–4 half-lives.

Insertion Kinetics for Norbornene

An NMR tube was charged with 0.7 mL of $[(\text{N}^{\wedge}\text{N})\text{Pd}(\text{Me})(\text{NCMe})]\text{BF}_4$ solution ($2.5 \times 10^{-2} \sim 1.1 \times 10^{-3}$ M) in CDCl_3 and tetramethylsilane (TMS) as internal standard, and then frozen with dry ice/acetone bath. Desired amount of norbornene (1.2 – 104.0 mg) was added directly. The sample was warmed briefly around the melting point of CDCl_3 and mixed by an iron stirrer. The tube was placed in a precooled NMR probe at desired temperature, and the decrease in intensity of Pd-Me for *cis*-isomers and Py H-4 or Py H-6 for *trans*-isomers were measured by using ^1H NMR spectroscopy. Spectra were taken at intervals of 46 – 301 sec. The slope of the line defined by the $\ln(\text{integral of Pd-Me, Py H-4 or Py H-6})$ signal vs time afforded the first-order rate constant, and the reaction was monitored for 2 – 4 half-lives.

Isomerization Kinetics

In a typical run, a single crystal of **C-2e** (3 mg, 4.9 μmol) was ground into powder, and then placed into an NMR tube with dry ice/acetone bath. CDCl_3 (0.7 mL) was added slowly at -78 °C in dry ice/acetone bath. The sample was warmed briefly and mixed by an iron stirrer around the melting point of CDCl_3 . The tube was placed in a precooled NMR probe at desired temperature, and the decrease in intensity of Py H-6 for *C*-isomer was measured by using ^1H NMR spectroscopy. Spectra were taken at intervals of 46–301 sec. The slope of the line defined by the $\ln(\text{integral of Py H-6})$ signal vs time afforded the first-order rate constant, and the reaction was monitored for 2–4 half-lives.

Its rate constant k_{isom} could be evaluated as 5.48×10^{-5} at 248 K, 2.52×10^{-4} and 3.15×10^{-4} at 253 K, 2.71×10^{-4} at 258 K, 7.83×10^{-4} at 263 K, 1.48×10^{-3} at 265.5 K, 1.80×10^{-3} at 268 K, and 5.69×10^{-3} at 273 K.

X-ray crystallographic analysis

Diffraction data were measured on a Nonius CAD-4, SmartCCD, or Nonius KappaCCD diffractometer with graphite-monochromatized Mo K_{α} radiation ($\lambda = 0.7103$ Å). No significant decay was observed during the data collection. The data were processed on a PC using the SHELXTL refinement software package.¹ The structures were solved using the direct method and refined by full-matrix least-squares on the F^2 value.

All the non-hydrogen atoms were refined anisotropically. Hydrogen atoms were identified by calculation and refined using a riding mode, and their contributions to structure factors were included. Atomic scattering factors were taken from the International Tables of Crystallographic Data, Vol IV. Computing programs are from the NRC VAX package.²

Computational Details

All geometries of the reactants, intermediates, transition states and products of reactions were fully optimized by using the Gaussian 09 program,³ and the B3LYP method with the LanL2DZ basis sets. No symmetry constrains were used for transition state optimization.^{4–5} Saddle points were determined by relaxed potential energy surface (PES) scan for bond

distance or dihedral angle. Harmonic vibration frequency calculations were performed on all stationary points to identify the local minimum (without imaginary frequency) or transition state (with one imaginary frequency), and determinate zero-point energies (ZPE). The relative energies ($E + ZPE$), obtained from vibrational frequency analyses on optimized structures by single point calculations, were corrected for basis set superposition error (BSSE)⁶ using the counterpoise method. Intrinsic reaction coordinate (IRC) calculations⁷ were also performed to confirm the connectivity between the transition state and the designed intermediates. The enantiomers are omitted for discussion, because they generally show nearly identical energies in the preliminary calculations.. The chirality of the coordinated amino group is fixed in *R*-form for the comparing purpose.

General procedure for copolymerization of ethylene-norbornene

Into a 600 mL Parr autoclave equipped with a magnetic stirring bar was placed norbornene (0.5-10 g) in dried CH_2Cl_2 (50 mL). The autoclave was sealed. Upon flush with ethylene gas several times, the ethylene gas was pressurized. The solution was stirred for 20 min in order to be saturated with ethylene gas. After release of ethylene pressure, the palladium complexes (0.06 mmol) were added, and then refilled with ethylene gas up to 21 bar. The mixture was stirred for 30 min, and the ethylene pressure was kept constant during the copolymerization runs. The reaction was quenched with venting the autoclave followed by adding 100 mL MeOH-HCl in 4:1 v/v ratio. The precipitated polymers were filtered from solution, washed with methanol and dried in vacuum oven at 80 °C overnight.

Fineman-Ross Plot

The copolymer compositions are determined according to the literature.⁹

Where Pd-N-polymer and Pd-E-polymer are the growing chain with norbornene and ethylene as the last inserted monomer, and the reactivity ratios are defined as $r_1 = k_{\text{NN}}/k_{\text{NE}}$ and $r_2 = k_{\text{EE}}/k_{\text{EN}}$. The r_1 represents the ratio of rate constants between the successive norbornene insertions and norbornene insertion followed by ethylene, and the r_2 represents the ratio of rate constants between the successive ethylene insertions and ethylene insertion followed by norbornene. By using quasi-steady-state assumption for propagation, the copolymer composition equation can be derived as:

$$\left(\frac{[\text{N}]}{[\text{E}]} \right)_{\text{polymer}} = \frac{[\text{N}]}{[\text{E}]} \frac{\left(1 + r_1 \frac{[\text{N}]}{[\text{E}]} \right)}{\left(r_2 + \frac{[\text{N}]}{[\text{E}]} \right)} \quad (3-10)$$

where $([E]/[N])_{\text{polymer}}$ and $([E]/[N])$ are the ethylene and norbornene molar ratios in the copolymer and the bulk reaction solution. Futher replacement of $([N]/[E])_{\text{polymer}}$ and $([N]/[E])$ to f and F , the following Fineman-Ross equation can be derived as:

$$\frac{(f - 1)}{f} F = r_1 \frac{F^2}{f} - r_2 \quad (3-11)$$

According to the N/E feeding ratios and norbornene calculated from ^{13}C NMR spectra in Table S1, the values of F and f in Eq. (3-11) are collected in Table S2. The Fineman-Ross data of E-N copolymerization catalyzed by **1e** give linear relationships between F^2/f and $F(f-1)/f$ as shown in Figure S1. Such data give the $r_1 = k_{\text{EE}}/k_{\text{EN}} = 0.013$, $r_2 = k_{\text{NN}}/k_{\text{NE}} = 0.31$ and $r_1 \times r_2 = 0.004$. The product of $r_1 \times r_2$ is significantly smaller than 1.0, indicating the consecutive hetero-olefin insertions are faster than the consecutive homo-olefin insertions.

Determination of norbornene content and alternating percentage for copolymers

The norbornene content, X_{NB} was evluated with use of ^{13}C NMR integrations as designated in the following table according to Eq. (1) used by Kaminsky.¹⁰

$$X_{\text{NB}} = \frac{I(\text{A})}{I(\text{B}) + I(\text{C}) + I(\text{D}) - 1.5 I(\text{A})} \quad (1-1)$$

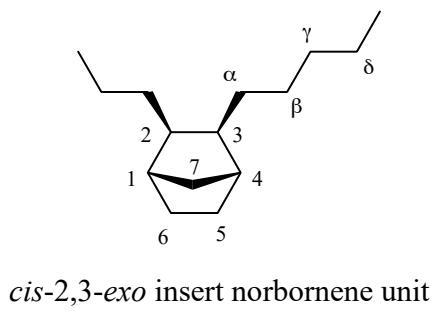

Table S5. Assignments of ethylene/norbornene copolymers in ^{13}C NMR spectra

Singnal area	δ (^{13}C NMR) (ppm)	Asignments
A	51 - 45	C2, C3
B	43 - 37	C1, C4
C	37 – 32.3	C7
D	32.3 - 28	C5, C6, C $_{\alpha}$, C $_{\beta}$, C $_{\gamma}$, C $_{\delta}$

The alternating percentage in a copolymer may be calculated according to Eq. (1-2).

$$\text{Alternating\%} = 2 \times \text{single NB mol \%} + \text{NB Diads mol \%} + 2/3 \times \text{NB Triads mol \%} \quad (1-2)$$

268	3.731343	1.67	0.512824

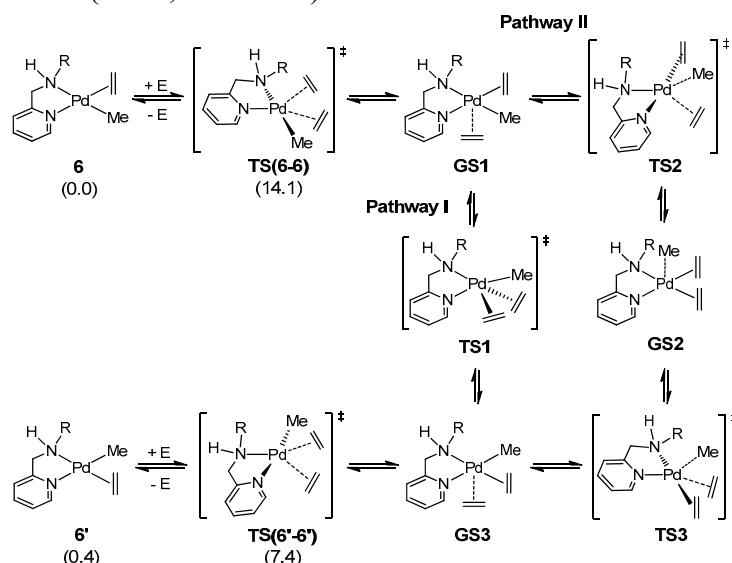

Figure S34. Van't Hoff plot and T/C ratios of **1e'**.

Theoretical Calculation

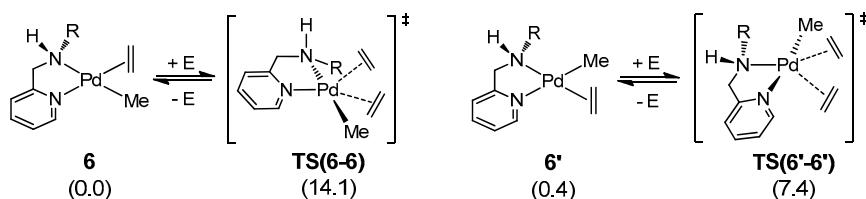

C-T isomerization

The first possible *C-T* isomerization is the ligand association-substitution reaction, involving square pyramidal intermediates, trigonal bipyramidal and square pyramidal transition states (Scheme S1).¹¹ Decrease of the distance for an external ethylene and palladium denoted as **6** and **6'**, respectively, affords the transition states **TS(6-6)** and **TS(6'-6')** in trigonal bipyramidal geometries, which the energies lie 14.1 and 7.0 kcal/mol above the **6** and **6'**, respectively (Scheme S2). Subsequent decrease of the ethylene-palladium distance resulted in the dissociation of original ethylene. Our trials to locate a ground state for **6** and **6'** with external ethylene in square pyramidal geometry resulted in a simple dissociation of ethylene. Relaxation of **TS(6-6)** and **TS(6'-6')** to the product sides give the **6** and **6'**, indicative of the ethylene exchange process. Such low ethylene exchange energies would result in the broadening signals in ¹H NMR spectra at low temperature, which are corresponded to the experimental observation. Therefore, the *C-T* isomerization via associative pathway has been ruled out.

Scheme S1. Possible *C-T* isomerization via Association-Substitution reaction ($E + ZPE$, kcal/mol). The GS1 and GS3 are not found. ($R = 2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3$)

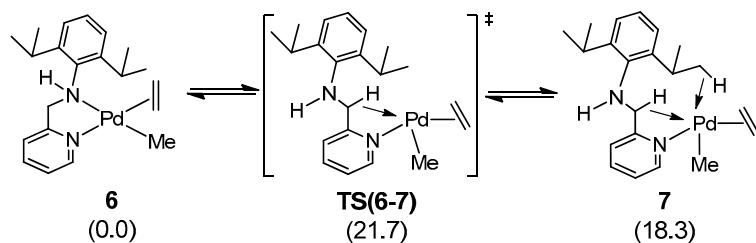

Scheme S2. Ethylene Exchange of $[(\text{Am-Py})\text{Pd}(\text{Me})(\text{C}_2\text{H}_4)]^+$ Complexes ($E + ZPE$, kcal/mol). ($R = 2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3$)

The second possible pathway is the ligand dissociation reaction. Increase of the ethylene-palladium distance could not find the local maximum or minimum. However, increase of the amine-palladium distance of **6** affords the transition states **TS(6-6)**

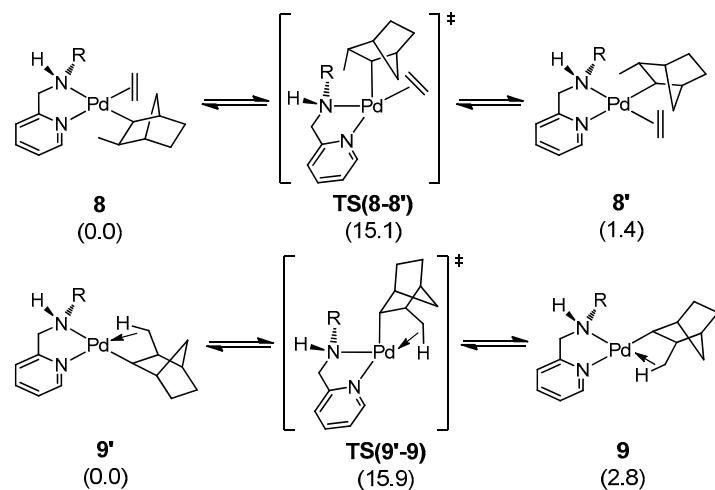

7) in trigonal pyramidal geometry, which is endothermic by 21.7 kcal/mol (Scheme S3). A weak δ -agostic interaction from $^{\text{t}}\text{Pr}$ group with the bond distance Pd-H = 2.5157 Å for **TS(6-7)** is found. The dissociative product **7** in trigonal bipyramidal geometry is lower in energy than **TS(6-7)** by 3.4 kcal/mol. The bond distances of Pd-H_{ax} and Pd-H_{eq} for **7** are 2.2027 and 2.5458 Å, respectively. Such value of energy barrier is comparable to the enthalpy of isomerization for norbornyl palladium complex (21.5 kcal/mol) in kinetic study.

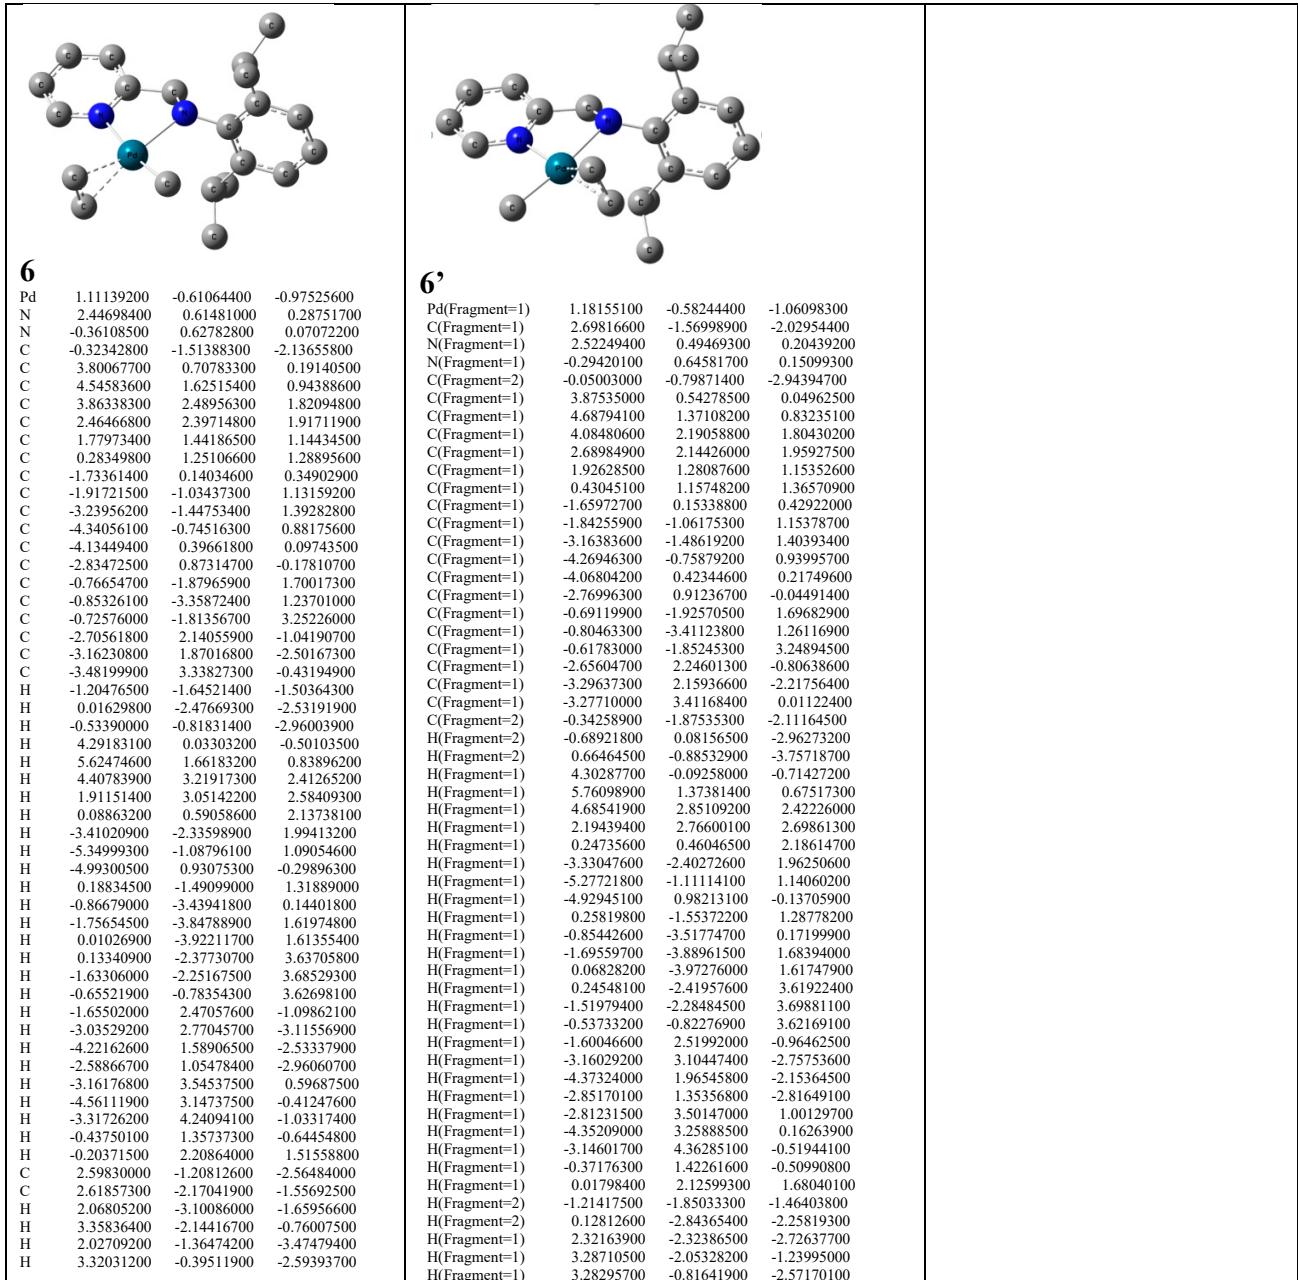

Scheme S3. *C-T* Isomerization via Amine Dissociation (E + ZPE, kcal/mol). (R = 2,6-*i*Pr₂C₆H₃)

The transition states of *C-T* isomerization via distorted tetrahedral geometry for norbornyl complex **8**, (Am-Py)Pd(C₇H₁₀Me)(C₂H₄), and γ -agostic complex **9'**, (am-py)Pd(C₇H₁₀Me), were also calculated (Scheme S4). The energies of **TS(8-8')** and **TS(9'-9)** lie 15.1 and 15.9 kcal/mol above the **8** and **9'**, respectively. The weak δ -agostic interactions of $^{\text{t}}\text{Pr}$ group for **TS(8-8')** and **TS(9'-9)** are observed with the bond distances Pd-H = 2.6270 and 2.2459 Å.

Scheme S4. *C-T* Isomerization via Distorted Tetrahedral Species for Norbornyl Complexes (E + ZPE, kcal/mol). (R = 2,6-*i*Pr₂C₆H₃)
