Abstract: Two new chromone-derived polyketides phaseolorins, G and H (**1** and **2**), and one new anthraquinone derivative, phaseolorin I (**3**), together with three known compounds (**4–6**), were isolated from the deep-sea sediment-derived fungus *Diaporthe phaseolorum* FS431. The structures of the new compounds were determined by comprehensive analysis of their spectroscopic data, and the absolute configuration of **1** was established by quantum chemical calculations of electron capture detection (ECD). All the isolated compounds (**1–6**) were tested for their in vitro cytotoxic activities against four human tumor cell lines, of which compound **4** exhibited significant effect against MCF-7, HepG-2, and A549 tumor cell lines with IC₅₀ values of 2.60, 2.55, and 4.64 μM, respectively.

Keywords: *Diaporthe phaseolorum*; deep-sea derived fungus; polyketides; cytotoxicity
