Figure S1. Venn diagram of probe sets that were differentially expressed. Cells were exposed to LIPUS (30 mW/cm², for 20 min), followed by culturing at 37 °C for six (A and B) and 12 h (C and D). Gene expression analysis of the probe sets that were upregulated (A and C) and downregulated (B and D) by a factor of 1.5 or greater was conducted using GeneSpring® software. The diagram shows the number of specifically and commonly expressed probe sets affected by LIPUS. The experiments were repeated three times.
