Lipid analysis by LC-MS

Lipid profiling were performed on the ACQUITY UPLC coupled with a Xevo G2-XS QTOF/MS detector (Waters Corp. Milford, MA, USA) using ACQUITY BEH C18 column (Waters Corp.) (Dimension 100 × 2.1 mm, 1.7 µm particle size) maintained at 55°C. For lipid profiling, the columns contained mobile phase solvent A (2:1:1 v/v 5mM ammonium acetate in water: acetonitrile: isopropanol), 20µM phosphoric acid and 0.05% acetic acid) and B (9:1v/v 5mM ammonium acetate in isopropanol: acetonitrile, 0.05% acetic acid) for establishing the optimized gradient as follows: 0 min, 1% B; 2 min, 40% B; 11.5 min, 95% B; 12.0–12.50 min, 99.9% B; 12.55 min, 65% B; 12.65 min, 30% B; 12.75-14.25 min, 1% B¹. Mass spectrometry analysis (QTOF/MS) was conducted in positive and negative ion modes as follows: capillary voltage, 2.0 kV/-1.5 kV; cone voltage 25; source temperature, 120°C; cone gas flow, 150 l/h; desolvation temperature and flow at 600°C and 1000 l/h; scan range, 50–2000 m/z; data acquisition rate, 0.1s and collision energy 4¹. Data was acquired using Masslynx 4.1 workstation and UPLC-QTOF/MS Acquisition software (Waters Company, Milford, MA, USA) in centroid mode and m/z values were adjusted by LockSpray using leucine-enkephalin as lock mass compound for the positive ([M + H]⁺ = 556.2771) and negative ([M - H]⁻ = 554.2615) ion modes respectively. The QC sample was injected 20 times before experiment to equilibrate the UPLC-MS system , further injection was done at the start, end and every 10th sample collection for reproducibility. A sequence of 24 diluted OC samples was injected during analysis run to detect “noise” in identified features. For targeted fatty acids LC-MS/MS analysis, the organic phase in ESI Negative form was employed. Elution gradient consist of mobile phase G (50:50 acetonitrile: water) and H (100% acetonitrile) was started with 65% mobile phase H, and linearly increased to 100% by 6 min and held for 3 min. Further 2 min equilibration was performed using initial conditions used for injection at 5 µl (flow rate 0.4 ml/min, 50°C). Statistical analysis was carried out using 2-way ANOVA followed by post-hoc multiple correction using FDR with Benjamini, Krieger and Yekutieli method ².

Metabolite profiling

Supernatants were analyzed using the BEH HILIC column (1.7 μ m, 2.1x100 mm) on an ACQUITY UPLC coupled with a Xevo G2-XS QTOF/MS detector (Waters Corp. Milford, MA, USA) using mobile phase C (20 mM ammonium formate, 0.1% formic acid) and D (acetonitrile, 0.1% formic acid) gradient at 0 min, 95% B; 4.6 min, 80% B; 5.5 min, 50% B; 7.10-12.65 min, 95% B¹. QTOF/MS acquisition parameters were as follows: capillary voltage, 1.5 kV; cone voltage 20; source temperature, 120°C; cone gas flow, 150 l/h; desolvation temperature 600°C and flow rate 1000 l/h; scan range, 50–2000 m/z; and collision energy 4.0. The QC samples were injected as described above under lipid profiling¹.

Metabolomics data processing and pathway analysis

Progenesis QI (V2.3) software was used for automatic data pre-processing, including retention time alignment, peak picking, deconvolution, and identification of features³. Retention time (RT)-mass/charge ratio (m/z) were used to characterize detected ions and placed into R (V3.4.2) for further data processing and statistical analysis. Locally estimated scatterplot smoothing (LOESS) regression was employed to correct for run order effects. Features were filtered according to the coefficient of variation (among QC injections) with correlation to dilution factors (among diluted QC injections). Principal component analysis (PCA) was employed to validate technical reproducibility of the analytical approach and visualize clustering, trends including outliers. Orthogonal partial least squares discriminant analysis (OPLS-DA) was next applied to screen differential variables responsible for differences between groups. Student's *t*-test was then used to further shortlist biomarker candidates based on FDR corrected *p*-values. Derived m/z values were matched to the putative metabolite using the online Metlin, HMDB and LipidMap databases and analyzed using MetaboAnalyst 4.0 pathway analysis⁴. Over Representation Analysis (ORA) was performed to assess for biologically meaningful patterns using the hypergeometric test and the adjusted one-tailed *p* values are provided after multiple testing. Pathway topology analysis was next performed using relative betweenness centrality to measure the number of shortest paths between node and global network topology. Disease enrichment pathway analysis was also carried out with disease-associated metabolite sets which consist of 344 metabolite sets reported in human blood, and we delineate pathway illustrating 2 or more compounds.

Table S4

Top significant ($p<0.05$) predictive metabolites and lipids in PEPs-exposed rat serum across the different days. For HILIC, samples were normalized using N-benzyl-d5-glycine (IS), 1.10_185.0972 m/z (positive mode) and 1.16_183.0816 m/z (negative mode). For reversed phase LC-MS, samples were normalised to PC (11:0/11:0), 3.22_594.4165 m/z; PG (15:0/15:0), 4.80_717.4709 m/z; Cer (d18:1/17:0), 6.89_534.5274 m/z; DG (19:0/0:0/19:0), 9.12_675.5926 m/z; PC (23:0/23:0), 9.70_930.7865 m/z (positive mode) and to C (17:0), 4.12_269.2484 m/z and PG (15:0/15:0), 4.81_693.4714 m/z (negative mode). Compound identification is based on Human Metabolome Database (HMDB) and Lipid Maps Database. Distribution analysis carried out using PCA and OPLS-DA plots and compound with significant p-value (<0.05) by ANOVA were illustrated.
