

Why sampling time was confirmed during August, 2016

Firstly, Honghu Lake is an important storage lake in Jianghan Plain. It is a semi-closed lake, and the inflows are mainly from the north through the Four-lake Main Canal. Outflow of Honghu Lake discharges into the Yangtze River through the only water gate in southeast, and the water gate is open only in flood period (generally in some days during June–August). Secondly, the rainfall in Honghu Basin is mainly concentrated in summer. The surface runoff in the area flows into Honghu Lake through the Four-lake Main Canal. Upstream water will also bring a large amount of pollutants into Honghu Lake, so the water pollution in flood period is more complicated than other seasons. Finally, during the flood period, Honghu Lake irregularly releases water as water levels rise. August is the end of the flood season, with relatively small fluctuations in water quality. Furthermore, the high water level in Honghu Lake during the flood season will bring inconvenience and danger to the sampling work. So at the preparation stage, we had a close communication with the local guide, environmental protection department and water conservancy department to keep abreast of the latest situation in Honghu Lake. We confirmed the sampling time at the end of the August when was about two weeks from the last water releasing time. Therefore, in our sampling date, the lake came into a relatively stable state. Based on the above, sampling time in this study was determined at the end of the August.

Table S1. Hazard quotient (HQ) and Hazard index (HI) of trace elements in surface water from Honghu Lake through ingestion.
