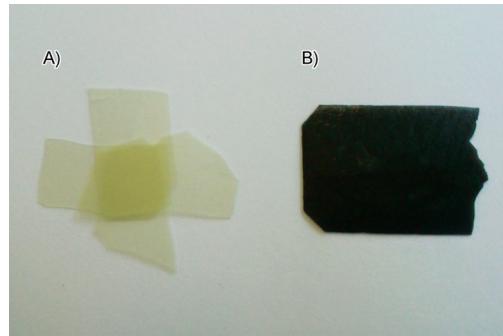

Figure S1. Comparison of the visual properties of (A) – stacked translucent porous alumina (a single layer thickness $\approx 70 \mu\text{m}$) and (B) – black opaque alumina of the equivalent layer thickness (280-300 μm).

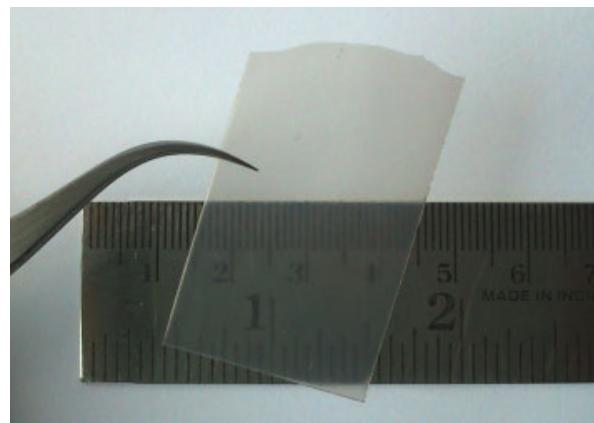

Figure S2: A photograph of the highly ordered and transparent PAA obtained from 0.3 M H_2SO_4 at $\Delta U = 27 \text{ V}$.

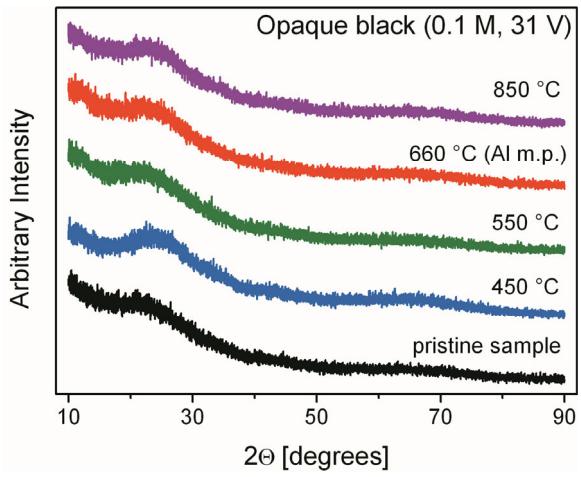

Figure S3: The XRD characterization of the thermally cured black opaque anodic alumina samples.

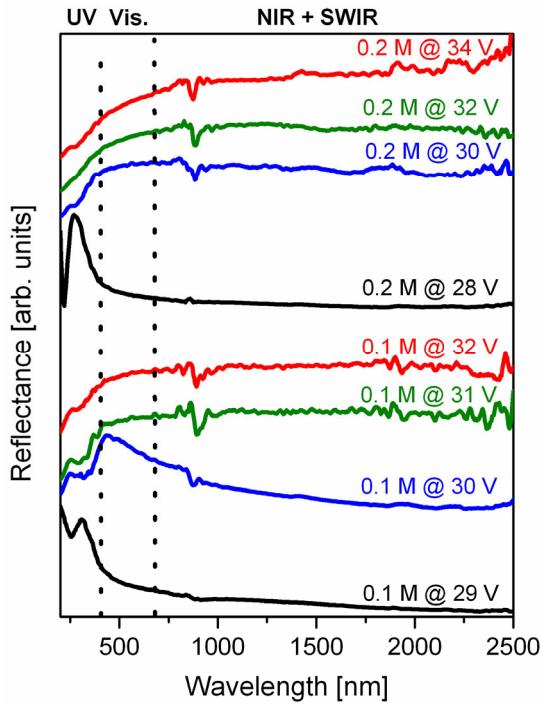

Figure S4: UV/Vis/NIR spectrometry results for PAA and b-PAA samples, which cover the UV, visible, near infrared (NIR) and short-wavelength infrared (SWIR) regions.
