

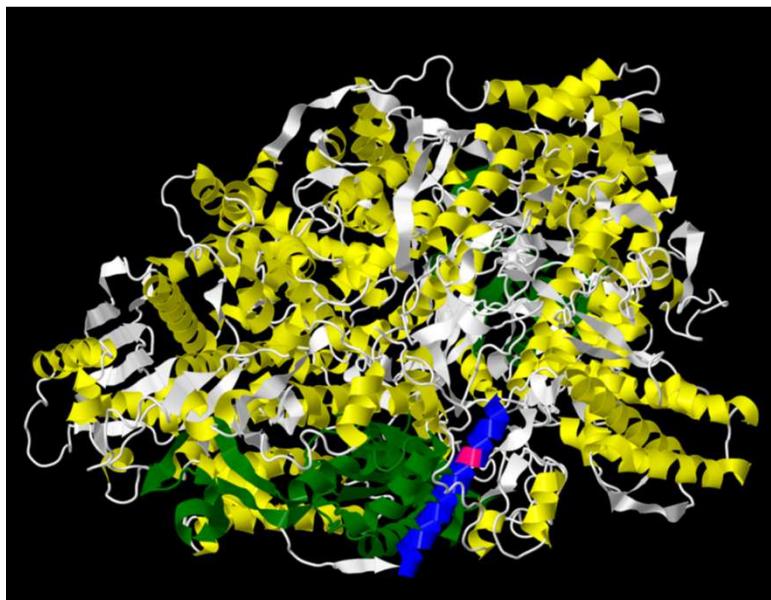

Figure S1. Plasmids' segments corresponding to recombinant virus antigenomes. The genomic regions in schemes are not drawn strictly to scale. Blue areas at the beginning and end of each gene indicate noncoding regions. P gene 5' noncoding region (NCR) and N gene 3' NCR are shown in different nuances in order to emphasize that they were included upstream and downstream of coding regions of additional transcription units (ATUs), respectively. In pF-RSV-MRV2 and pE1E2TMD-HCV-MRV2, striped areas indicate transmembrane and cytoplasmic region of mumps virus F glycoprotein, which was added to ectoplasmic domains of RSV F, and HCV E1 and E2 proteins. ATUs are shown in green, orange and yellow; regions with alternative synonymous sequences are shown in purple. The 3' NCR of HN gene in pmiscr-MRV3 is shown lengthened, to indicate addition of 84 nucleotides.

A) 408 Leu

B) 408 Pro

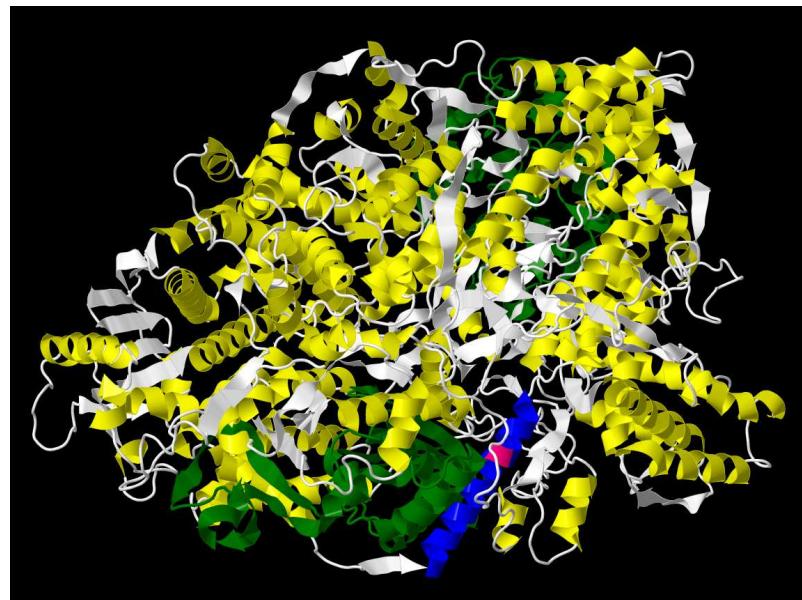

Figure S2. Mumps virus L protein models. The two L protein primary sequences differ only at amino acid 408 (leucine in figure A, proline in figure B). Models were generated using SWISS-MODEL homology-modelling server and visualized using Geneious Prime® 2019.2.3 software. Alpha-helix that extends from amino acid 394 to amino acid 416 is shown in blue, with amino acid 408 in red. Other α -helices are shown in yellow. Green colour indicates two L protein's catalytic regions: RNA-dependent RNA-polymerase and 2'-O-methyltransferase, shown in the lower left and upper right corner, respectively. Their positions were annotated according to UniProtKB entry P30929.

Table S4. Positions and frequencies of nucleotide substitutions and corresponding amino acid changes in primary viral rescue stocks. The substitutions indicate the difference from input plasmid sequence (the first nucleotide/amino acid is the identity in plasmid). For synonymous substitutions only the number of corresponding amino acid is shown. ForMRV3, F-RSV-MRV2, E1E2TMD-HCV-MRV2 and *mrscr*MRV3 only the regions of mumps virus backbone (not the insert(s)) are included in the analysis, their genomic positions are adjusted to corresponding positions in MRV2. Substitutions present in viral population consensus sequence (present in more than 50% of reads) are indicated in bold.
