

Supplemental Files

Expanded results on 1) tetracycline (TTCC) biomarker observed, 2) generalized liner mixed modeling (GLMM) for rabies virus neutralizing antibodies (RVNA) at 0.5 IU/mL cutoff, for TTCC, and for model selection, and 3) generalized additive modeling (GAM) for RVNA at 0.5 IU/mL cutoff and TTCC biomarker.

Results

Tetracycline (TTCC) biomarker observed

Average pre-ORV prevalence of TTCC marked animals in the study area with a prior ONRAB standard density ORV (75 baits/km²; years 2012-2014) was 30.3% (248/818 95% CI: 27.3-33.6%) for raccoon and 0.0% (0/33, 95% CI: 0-10.4%) for skunk populations. Average post-ORV prevalence of TTCC marked animals during standard density (75 baits/km²) ORV during 2012-2013 was 40.7% (201/494, 95% CI: 36.5-45.1%) among raccoon and 0.2% (1/52, 95% CI: 0.0-10.1%) among skunk populations. Average pre-ORV prevalence of TTCC marked animals during high density ORV (300 baits/km²; years 2015-2016) was 69.6% (311/447, 95% CI: 65.2-73.7%) for raccoon and 30.4% (7/23, 95% CI: 1.6-50.9%) for skunk populations. Average post-ORV prevalence of TTCC marked animals at the high density ORV was 74.9% (427/570, 95% CI: 71.2-78.3%) for raccoon and 24.0% (23/96, 95% CI: 1.7-33.4%) for skunk populations (Figure S1).

Generalized liner mixed modeling (GLMM)

RVNA seroprevalence 0.5 IU/mL cutoff

Modeling the response data at the 0.125 IU/mL and the 0.5 IU/mL cutoff resulted in similar trends for the GLMM, but the estimates in seroprevalence was lower at the 0.5 IU/mL for both the raccoon and skunk populations. The GLMM at the 0.5 IU/mL indicated positive relationships between bait density and levels of RVNA among raccoon and skunk populations (Table S5, Figure S3). Among raccoon populations, the estimated seroprevalence increased post-ORV from 39% (95% CI: 36-42%) using 75 baits/km² to 74% (95% CI: 71-77%) using 300 baits/km². Among skunk populations, the estimated seroprevalence increased post-ORV from 11% (95% CI: 10-11%) at 75 baits/km² to 27% (95% CI: 24-31%) at 300 baits/km².

TTCC response

Examination of TTCC in the raccoon and skunk populations indicated the same trend as the seroprevalence models, specifically that more animals were positively marked at 300 baits/km² than at 75 baits/km² (Figure S8). Among raccoon populations, the estimated marking prevalence increased post-ORV from 13% (95% CI: 11-14%) using 75 baits/km² to 53% (95% CI: 48-59%) using 300 baits/km². Among skunk populations, the estimated marking prevalence increased post-ORV from 9% (95% CI: 6-12%) at 75 baits/km² to 28% (95% CI: 15-42%) at 300 baits/km². Compared with the covariate estimates at the 0.125 IU/mL cutoff (Table 3) and the 0.5 IU/mL cutoff (Table S5), the TTCC bait density covariate estimate was higher for both raccoons and skunks (Table S10). Additionally, for the skunks the graph indicate an increase in marked prevalence post-ORV as years of baiting increase, especially at the 300 baits/km².

Model selection

We compared nine models in our GLMM analysis to identify the factors influencing seroprevalence at both the 0.125 IU/mL and 0.5 IU/mL cutoff for both raccoons and skunks (Table S11). Only one competitive model existed for raccoons when the response variable was seroprevalence at 0.125 IU/mL cutoff (Table S12) and at the 0.5 IU/mL (Table S13) and its was the same model for both cut-offs. This model contained bait density and the two-way interaction years of baiting $\times$ period indicating that all of these factors compared were important to the seroprevalence. Four competitive models existed for skunks at 0.125 IU/mL (Table S14). The top model contained the individual variables bait density and years of bating indicating that of the factors compared, both variables were significantly impacting seroprevalence. One

competitive model existed for skunks at 0.5 IU/mL (Table S15), which contained bait density and period (Table S15).

Generalized additive modeling (GAM)

RVNA seroprevalence 0.5 IU/mL cutoff

At the 0.5 IU/mL cutoff, we observed three competitive models for raccoons (Table S16) and three for skunks (Table S17). The top raccoon model was the same as the 0.125 IU/mL cutoff and contained sex and age as well as two two-way interactions: period $\times$ age and bait density $\times$ years for baiting (Table S18). They had the same relationship associated with whether an individual would likely be positive as the top model at the 0.125 IU/mL cutoff. The top skunk model contained the two-way interaction bait density $\times$ years for baiting and the main effects age and period (Table S19). When these effects could be compared, the relationship with period was the same as the top model at the 0.125 IU/mL cutoff; the other factors, the interaction and age, were not in that model. An individual skunk captured in the post-ORV period and associated with a bait density of 300 baits/km² was more likely to be seropositive. Older skunks were also more likely to be seropositive.

TTCC biomarker

We compared 75 models in our GAM analysis to identify factors influencing individual-animal seroprevalence at both the 0.125 IU/mL and 0.5 IU/mL cutoff for both raccoons and skunks. We used the same 75 models to identify factors influence TTCC biomarking at the individual-animal level (Table S2). We observed one competitive model for raccoons (Table S20) and four competitive models for skunks (Table S21). The raccoon top model was the full model tested (Table S22). For the effects that could be directly compared in the top models, the interaction term bait density $\times$ years of baiting had the same association as the model evaluating seroprevalence at 0.125 IU/mL and at 0.5 IU/mL. The skunk top model contained one two-way interaction of period $\times$ age and included the variables bait density, and years of baiting (Table S23). Compared with the top model for seroprevalence at 0.125 IU/mL, the effects that could be compared, bait density and years of baiting, had the same trends; a skunk was more likely to be positive at the 300 baits/km² and after more years of baiting.

Summary

Our additional evaluations continued to support higher seroprevalence at 300 baits/km² compared to 75 baits/km² for both raccoons and skunks. The analysis of the biomarker also supported trends we observed with the seroprevalence data.

Figures

Figure S1: Raccoon (a) and skunk (b) rabies virus neutralizing antibody (RVNA) seroprevalence from oral rabies vaccination (ORV) field trials with Ontario Rabies Vaccine Baits (ONRAB) in West Virginia, USA in relationship to bait density, sampling period (pre- or post-ORV), year. RVNA cutoff observed was 0.5 IU/mL. Error bars reflect the 95% confidence interval.

Figure S2: Proportion of (a) raccoons and (b) skunks positive for tetracycline hydrochloride (TTCC) biomarker from the oral rabies vaccination (ORV) field trials with Ontario Rabies Vaccine Baits (ONRAB) in West Virginia, USA in relationship to bait density, sampling period (pre- or post-ORV), and year. A total of 2,329 samples from raccoons and 204 samples from skunks were evaluated. Error bars reflect the 95% confidence interval.

Figure S3: Estimated raccoon and skunk rabies virus neutralizing antibody (RVNA) seroprevalence from oral rabies vaccination (ORV) field trials with Ontario Rabies Vaccine Baits (ONRAB) in West Virginia, USA in relationship to bait density, sampling period (pre- or post-ORV), and year. Estimates were from a beta regression analysis using RVNA cutoffs at 0.125 IU/mL (a: raccoons and b: skunks) and at 0.5 IU/mL (c: raccoons and d: skunks). Shading represents the 95% confidence interval.

Figure S4: Proportion of skunks seropositive for rabies virus neutralizing antibodies (RVNA) at a cutoff of 0.125 IU/mL by age and bait densities sampled pre- and post-oral rabies vaccination (ORV) in West Virginia, USA. Error bars represent 95% confidence intervals.

Figure S5: Proportion of skunks seropositive for rabies virus neutralizing antibodies (RVNA) at a cutoff of 0.125 IU/mL by sex and bait densities sampled pre- and post-oral rabies vaccination (ORV) in West Virginia, USA. Error bars represent 95% confidence intervals.

Figure S6: Histogram of raccoon (n=2,296) ages based on cementum annuli of premolar teeth from the oral rabies vaccination (ORV) field trials with Ontario Rabies Vaccine Baits (ONRAB) in West Virginia, USA. The oldest raccoon was 15 years old.

Figure S7: Histogram of skunk (n=192) ages based on cementum annuli of premolar teeth from the oral rabies vaccination (ORV) field trials with Ontario Rabies Vaccine Baits (ONRAB) in West Virginia, USA. The oldest skunk was 4 years old.

Figure S8: Estimated prevalence of the biomarker tetracycline hydrochloride (TTCC) in raccoon (a) and skunk (b) populations from oral rabies vaccination (ORV) field trials with Ontario Rabies Vaccine Baits (ONRAB) in West Virginia, USA in relationship to bait density, sampling period (pre- or post-ORV), and year. Estimates were from a beta regression analysis and shading represents the 95% confidence interval.

Tables

Table S1: Comparison of rabies virus neutralizing antibody (RVNA) results for a subset of raccoon and skunk serum samples tested at New York State Department of Health (NYSDOH; lab 1) and Kansas State University (lab 2). The RVNA titers were determined from all raccoon and skunk samples at NYSDOH using a cutoff at 0.125 IU/mL. A subset of 300 raccoon samples and 39 skunk samples were tested at lab 2, which used a cutoff of 0.1 IU/mL.

Species	RVNA results at lab 1	Number of samples in study	Number tested by lab 2	Number RVNA positive at lab 2	RVNA agreement between labs 1 and 2
Raccoon (<i>Procyon lotor</i>)					
	<0.125	1053	n.t	n.t	n.t
	0.125	218	100	15	15%

	0.5	244	100	91	91%
	>=1	1162	n.t	n.t	n.t
Striped skunks (<i>Mephitis mephitis</i>)					
	<0.125	215	n.t	n.t	n.t
	0.125	18	18	4	22%
	0.25	10	10	8	80%
	0.5	11	11	8	73%
	>=1	36	n.t	n.t	n.t

Table S2: The models compared for the individual level generalized additive modeling analysis for the raccoons and skunks. The same models were used for both species and with three different response variables; which were 1) rabies virus neutralizing antibodies (RVNA) with a seropositive cutoff at 0.125 IU/mL, 2) RVNA at 0.5 IU/mL cutoff, and 3) prevalence of the tetracycline biomarker. Within the structure of the models, “*” indicates both an additive and interaction of the variables surrounding the “*”.

Table S3. Information on target species sampling (n), rabies virus neutralizing antibody (RVNA) seroprevalence (%) at 0.125 IU/mL cutoff and 95% confidence interval for oral rabies vaccination with Ontario Rabies Vaccine Baits (ONRAB) at 75 baits/km² in 2012-2013 and at 300 baits/km² in 2014-2016 in West Virginia, USA. Due to sequential baiting in the cells for the different bait densities, the year 2014 was split; the pre-ORV trapping period had previously been baited at 75 baits/km² and it was only the post-ORV trapping period that followed baiting at 300 baits/km².

Table S6: Model selection table of the individual level generalized additive modeling candidate model set for raccoon seroprevalence at the 0.125 IU/mL cutoff. Models are sorted from most parsimonious on top to least parsimonious based on Akaike's information criterion corrected (AICc) for small sample sizes. The model names, degrees of freedom (df), the log likelihood (LL), the AICc, the delta AICc (difference between the model AICc value and the top model), the model likelihood (ModelLik), the AICc weight (relative support for each model), and the cumulative AICc weight (Cum.Wt, representing total cumulative weight for the given model and all models above it) are shown.

Table S7: Model selection table of the individual level generalized additive modeling candidate model set for skunk seroprevalence at the 0.125 IU/mL cutoff. Models are sorted from most parsimonious on top to least parsimonious based on Akaike's information criterion corrected (AICc) for small sample sizes. The model names, degrees of freedom (df), the log likelihood (LL), the AICc, the delta AICc (difference between the model AICc value and the top model), the model likelihood (ModelLik), the AICc weight (relative support for each model), and the cumulative AICc weight (Cum.Wt, representing total cumulative weight for the given model and all models above it) are shown.

Table S11: The models compared for the generalized liner mixed model analysis for the raccoons and skunks. The same models were used for both species and with two different response variables; which were 1) rabies virus neutralizing antibodies (RVNA) with a seropositive cutoff at 0.125 IU/mL and 2) RVNA at 0.5 IU/mL cutoff. Within the structure of the models, “*” indicates both an additive and interaction of the variables surrounding the “*”.

Table S20: Model selection table of the individual level generalized additive modeling candidate model set for raccoons based on detection of the tetracycline biomarker. Models are sorted from most parsimonious on top to least parsimonious based on Akaike's information criterion (AICc) corrected for small sample sizes. The model names, degrees of freedom (df), the log likelihood (LL), the AICc, the delta AICc (difference between the model AICc value and the top model), the model likelihood(ModelLik), the AICc weight (relative support for each model), and the cumulative AICc weight (Cum.Wt, representing total cumulative weight for the given model and all models above it) are shown.
