#### Abstract

The hit compound 1,2,4-triazolo[ $\left.4^{\prime}, 3^{\prime}: 2,3\right]$ pyridazino[4,5-b]indole 3 was synthesized from the reflux of 4-amino-5-indolyl-1,2,4-triazole-3-thione $\mathbf{1}$ with $4^{\prime}$-bromoacetophenone 2 in methanol catalyzed by concentrated HCl and the desired final molecule was obtained by recrystallization from methanol. The suggested structures of compounds 1 and 3 based on the spectral characterizations were confirmed by X-ray single crystal diffraction analysis. Compound 3 crystallized in the triclinic crystal system and $P-1$ space group with $a=5.9308(2) \AA, b=10.9695(3) \AA, c=14.7966(4) \AA$, $\alpha=100.5010(10)^{\circ}, \beta=98.6180(10)^{\circ}$, and $\gamma=103.8180(10)^{\circ}$. On the other hand, the crystal system of 1 is monoclinic, where $a=6.23510(10) ~ \AA, b=26.0156(4) ~ \AA, c=12.4864(2) \AA, \beta=93.243(2)^{\circ}$ and the space group is $P 2_{1}$. The triazole and indole rings are found twisted from each other in both compounds. The twist angle is higher in $3\left(12.65^{\circ}\right)$ than $\mathbf{1}\left(4.94-7.22^{\circ}\right)$. In the case of the former, the H $\ldots \mathrm{H}(39.6 \%), \mathrm{H} \ldots \mathrm{C}(22.0 \%), \mathrm{N} \ldots \mathrm{H}(12.8 \%)$ and $\mathrm{Br} \ldots \mathrm{H}(13.2 \%)$ contacts are the most dominant while the $\mathrm{C} \ldots \mathrm{C}, \mathrm{C} \ldots \mathrm{H}, \mathrm{Br} \ldots \mathrm{H}, \mathrm{N} \ldots \mathrm{H}$ and $\mathrm{S} \ldots \mathrm{S}$ contacts have the characteristics of strong interactions. In the latter, the C $\ldots \mathrm{H}, \mathrm{N} \ldots \mathrm{H}, \mathrm{S} \ldots \mathrm{H}, \mathrm{S} \ldots \mathrm{S}$, and $\mathrm{C} \ldots \mathrm{C}$ contacts are the most important. In this case, the percentages of the $\mathrm{H} \ldots \mathrm{H}, \mathrm{C} \ldots \mathrm{H}, \mathrm{N} \ldots \mathrm{H}$ and $\mathrm{S} \ldots \mathrm{H}$ contacts are in the range of $34.9-37.4,20.5-24.0,12.2-13.6,14.0-15.8$, respectively. In both systems, the shape index and curvedness of surfaces confirmed the presence of $\pi-\pi$ stacking interactions.

Keywords: pyridazino[4,5-b]indol-4-one; indoles; pyridazines; X-ray single crystal; Hirshfeld surface analysis

## 1. Introduction

Among the poly nitrogen containing compounds, whose importance in the field of biology and smart materials is well known [1,2], it is worth mentioning the pyridazino[4,5$b$ ]indol-4-ones, which are a class of heterocycles consisting of fused tricyclic rings having pyridazine and indolyl scaffolds. This conjugate has been determined to be an interesting pharmacophore in drug discovery research. In cancer treatment, in particular the pyridazino[4,5-b]indol-4-one as an aza-heterocycle class compound exhibited high efficacy against many human cancer cells and targeted PI3K $\alpha$ and DYRK1A5 inhibitory activity [3,4]. Many other biological features have been reported for the pyridazino[4,5-b]indol-4-ones as anti-microbial agents [5,6], anti-hypertensive [7,8], anti-viral (HIV-1) [9] and blood platelet aggregation inhibitors [10]. Additionally, pyridazino[4,5-b]indol-4-one which can be classified as $\beta$-carboline or $\gamma$-carboline core structures, showed interesting
pharmacological potencies [11] such as binding with DNA, genotoxic, mutagenic and cytotoxicity activities [12]. To design new molecules based on pyridazino[4,5-b]indol-4-one as a pharmacological feature is an attractive challenge.

Many representative examples reported so far derive from the pyridazino[4,5-b]indol-4one carboline framework structure, such as SSR180575 (Figure 1) which is a neuroprotective agent targeted to TSPO or PBR receptors with high nanomolar binding affinity [13,14]. ZFD-10 is another representative example which was reported recently to be an anti-viral agent against ZIKV [15]. The authors claimed that this compound was able to inhibit the ZIKV NS5 RdRp receptor and confirmed this using an RNA polymerase assay [15]. Sarhan, et al., designed and evaluated a novel pyridazino[4,5-b]indol-4-one derivative against the human breast cancer cell (MCF-7), and was identified as a phosphoinositide 3-kinase (PI3K) inhibitor [16]. Besirli and co-workers developed a small molecule as a next generation PKM2 activator, signaling photoreceptor apoptosis [17]. Salama and co-workers have identified new molecules based on pyridazino[4,5-b]indol-4-one as multitargeting inhibitors binding targets including EGFR, PI3K, and AKT [18].

Pergolide

Figure 1. Some pyridazino[4,5-b]indol-4-one derivatives and selected thioether drugs of biological importance.

Many other biological activities have been reported to be targeted by pyridazino[4,5-b]indol-4-one [19-27], such as neoplastic progression, neuroinflammation, acute and chronic inflammation, congestive heart failure (CHF), antiarrhythmic, serotonin antagonists [28-30], among others. Thioether drugs represents one of the most important constituents of sulfur containing drugs. The demonstrative pharmaceutical drugs include cimetidine (mainly used for treatment of heartburn and peptic ulcers), thiethylperazine (important antagonist of dopamine receptors), and pergolide (ergoline-based dopamine receptor agonist used in some countries for the treatment of Parkinson's disease) [31,32].

Based on these findings mentioned above and in continuation of our research program for the synthesis of novel heterocycles, we report here new pyridazino[4,5-b]indol-4-one derivatives. The chemical architectures were assigned based on a single crystal X-ray diffraction analysis and other spectrophotometric tools. Additionally, supramolecular insights have been explored using Hirshfeld surface analysis.

## 2. Materials and Methods

Melting points were determined using melting-point apparatus (SMP10) in open capillaries and are uncorrected. Chemicals, solvents and reagents were purchased from Sigma-Merck (Burlington, MA, USA) and Alfa Aesar (Stoughton, MA, USA). The reaction progress and product purity was observed by thin layer chromatography (TLC) pre-coated plates with silica gel $60 \mathrm{~F}_{254}$ with a thickness of 0.25 mm (Merck). Nuclear magnetic reso-
nance ( ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR) spectra were determined in DMSO- $d_{6}$ and were recorded on Bruker AC 400 MHz spectrometers (Billerica, MA, USA) using TMS as an internal reference standard. $\delta(\mathrm{ppm})$ was used for chemical shift description and values of coupling constants were given in Hz. CHNS-microanalysis was performed on a Flash EA-1112 instrument (Thermo Fisher Scientific, San Diego, CA, USA).

### 2.1. X-ray Structure Determinations

The crystals of $\mathbf{1}$ and $\mathbf{3}$ were immersed in cryo-oil, mounted on a loop, and measured at a temperature of 120 K and 170 K , respectively. The X-ray diffraction data were collected on a Bruker Kappa Apex II (3) or a Rigaku Oxford Diffraction Supernova (1) diffractometer using Mo K $\alpha$ radiation. The Denzo-Scalepack [34] (3) or CrysAlisPro [35] (1) software packages were used for cell refinements and data reductions. The structures were solved by the intrinsic phasing method using the SHELXT [36] software. A numerical (3) absorption correction (SADABS [37]) or Gaussian (1) absorption correction (CrysAlisPro [33]) was applied to the intensities before the structure solution. Structural refinements were carried out using SHELXL [38] software with the SHELXLE [39] graphical user interface. The crystal of 1 was solved in the chiral space group $P 2_{1}$ and the asymmetric unit contained four crystallographically independent molecules. The $\mathrm{NH}^{2}$ and $\mathrm{NH}_{2}$ hydrogen atoms were located from the difference Fourier map and refined isotopically. All other hydrogen atoms were positioned geometrically and constrained to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}=0.95-0.98 \AA$ and $\mathrm{U}_{\text {iso }}=1.2-1.5 \cdot \mathrm{U}_{\text {eq }}$ (parent atom). The crystallographic details are summarized in Table 1.

### 2.2. Hirshfeld Surface Analysis

The topology analyses were performed using the Crystal Explorer 17.5 program [40].

## 3. Results and Discussion

The starting precursor 4-amino-5-(1H-indol-2-yl)-2,4-dihydro-3H-1,2,4-triazole-3-thione 1 was synthesized following the procedures outlined previously [33]. Reaction of $\mathbf{1}$ with $4^{\prime}$-bromoacetophenone 2 in methanol and the presence of concentrated HCl as an acid catalyst afforded 1,2,4-triazolo $\left[4^{\prime}, 3^{\prime}: 2,3\right]$ pyridazino[4,5-b]indole 3 in good yield (Scheme 1).

Scheme 1. Synthesis of 1,2,4-Triazolo $\left[4^{\prime}, 3^{\prime}: 2,3\right]$ pyridazino[4,5-b]indole 3.
The NMR supported the structure (see Figures S1-S4; Supplementary Materials) via the following signals: ${ }^{1} \mathrm{H}$ NMR displayed the triazole NH at 14.01 ppm , the indole NH at 11.77 ppm and the amino group protons at 5.97 ppm . In addition, ${ }^{13} \mathrm{C}$ NMR detected the thiocarbonyl carbon at 167.08 ppm and the remaining triazole carbon at 144.93 ppm . The ${ }^{1} \mathrm{H}$ NMR of 3 displayed a signal at 12.43 ppm for indole NH, and two signals at 2.66 and 2.01 ppm for two methyl groups. Moreover, ${ }^{13} \mathrm{C}$ NMR displayed the two triazole carbons at 150.20 and 146.44 ppm . The quaternary carbon was detected at 61.88 ppm . While the two methyl carbons were found at 27.27 and 13.76 ppm .

The reaction product 3 is suggested to form through the mechanism described in Scheme 2. The mechanism illustrates the role of the acid catalyst in the condensation reaction and removal of a water molecule. Secondly the mechanism also explains the role of the acid in the formation of an electrophile (the expected methyl carbocation) from
methanol as a methylating agent which then attacked from the nucleophilic sulfur atom (Scheme 2).

Scheme 2. Plausible mechanism for the synthesis of compound 3.

### 3.1. Crystal Structure Description

The structure of $\mathbf{3}$ is further confirmed using X-ray diffraction of a single crystal. The structure of the asymmetric unit is shown in Figure 2. As seen in this figure, there is one molecule of 3 as an asymmetric formula while four molecules are present in the unit cell. Compound 3 crystallized in the triclinic crystal system and $P-1$ space group. The unit cell parameters are $a=5.9308(2) \AA, b=10.9695(3) \AA, c=14.7966(4) \AA, \alpha=100.5010(10)^{\circ}$, $\beta=98.6180(10)^{\circ}$, and $\gamma=103.8180(10)^{\circ}$, while $\mathrm{V}=900.07(5) \AA^{3}$ and density is calculated to be $1.573 \mathrm{mg} / \mathrm{m}^{3}$ (Table 1). The experimental geometric parameters are depicted in Table 2. The triazole and indole rings are perfectly planar but both rings are twisted from each other by $12.65^{\circ}$. In addition, the phenyl ring is nearly perpendicular to the mean plane of the triazole and indole moieties. The corresponding twist angles are 83.71 and $86.57^{\circ}$, respectively.

Figure 2. X-ray structure of 3.

Table 2. Bond lengths $(\AA)$ and angles $\left({ }^{\circ}\right)$ of 3.

The molecular units of 3 are connected to each other by C13-H13C ... N2, N4-H4 $\ldots$ N1 and N3-H3 ... N2 non-covalent interactions shown in Figure 3A. Details of these intermolecular interactions are depicted in Table 3. The H13C ... N2, H4 ... N1 and H3 ... N2 have the shortest interaction distances of $2.54,2.46(3)$ and $2.07(3) \AA$, respectively, while the C13 . . N2, N4 . . . N1 and N3 . . . N2 distances are 3.458(3), 3.270(2) and 2.854(2) $\AA$, respectively. The corresponding C13-H13C . . N2, N4-H4 ... N1 and N3-H3 . . N2 angles are $155.7,160(2)$ and $172(3)^{\circ}$, respectively. The packing scheme of the molecular units is shown in Figure 3B.

Figure 3. The C-H . . . N/N-H . . . N contacts (A) and molecular packing scheme (B) for 3.

Table 3. Hydrogen bonds for 3 [ $\AA$ and ${ }^{\circ}$ ].

| D-H $\ldots$ A | $\mathrm{d}(\mathrm{D}-\mathrm{H})$ | $\mathrm{d}(\mathbf{H} \ldots \mathbf{A})$ | $\mathrm{d}(\mathbf{D} \ldots \mathbf{A})$ | $<(\mathrm{DHA})$ | Symm. Code |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{N}(3)-\mathrm{H}(3) \ldots \mathrm{N}(2) \# 1$ | $0.79(3)$ | $2.07(3)$ | $2.854(2)$ | $174(3)$ | $\# 1-\mathrm{x}+1,-\mathrm{y}+$ |
| $\mathrm{C}(13)-\mathrm{H}(13 \mathrm{C}) \ldots \mathrm{N}(2) \# 2$ | 0.98 | 2.54 | $3.458(3)$ | 155.7 | $\# 2,-\mathrm{z}+1$ |
| $\mathrm{~N}(4)-\mathrm{H}(4) \ldots \mathrm{N}(1) \# 2$ | $0.85(3)$ | $2.46(3)$ | $3.270(2)$ | $160(2)$ | $\# 2 \mathrm{x}+1, \mathrm{y}, \mathrm{z}$ |

In addition, the supramolecular structure of 3 is controlled by C-H $\ldots \pi$ interactions between the C13-H13C of the methyl group and the $\pi$-system of the triazole system. The distance between the H 13 C atom and the ring centroid is 2.432 (3) $\AA$. Presentation of the C-H . . . $\pi$ interactions is shown in Figure 4.

Figure 4. The C-H ... $\pi$ interactions in 3.
On the other hand, the X-ray structure of $\mathbf{1}$ is shown in Figure 5 while the detailed crystal data are given in Table 1. The crystal system of compound $\mathbf{1}$ is the more symmetric monoclinic and $P 2_{1}$ space group. Crystal data are $a=6.23510(10) \AA, b=26.0156(4) \AA$, $c=12.4864(2) \AA$, and $\beta=93.243(2)^{\circ}$, while $V=2022.17(6) \AA^{3}$ and $z=8$. The crystal density is calculated to be $1.519 \mathrm{mg} / \mathrm{m}^{3}$. In this crystal structure, there are four molecules of this compound that differ very little in their geometric parameters (Table 4). In this case, the twist angles between the indole and triazole rings are found to be less compared to 3, where the twist angles are $7.22,4.94,6.74$, and $6.21^{\circ}$, for molecules $\mathbf{A}$ to $\mathbf{D}$, respectively.

Figure 5. Structure of the four molecules in the asymmetric formula of 1 .

The molecular packing of $\mathbf{1}$ is presented in Figure 6 while the hydrogen bond parameters are depicted in Table 5. There are a large number of polar $\mathrm{N}-\mathrm{H} \ldots \mathrm{N}$ and $\mathrm{N}-\mathrm{H} \ldots$ S hydrogen bonds which connect the molecules of compound 1 via complicated sets of hydrogen bonding interactions. The donor-acceptor distances for the $\mathrm{N}-\mathrm{H} . . . \mathrm{N}$ hydrogen bonds are in the range of $3.010(4) \AA(\mathrm{N} 3-\mathrm{H} 3 \mathrm{~B} \ldots \mathrm{~N} 5)$ to $3.157(4) \AA(\mathrm{N} 1 \mathrm{C}-\mathrm{H} 1 \mathrm{C} . . . \mathrm{N} 3 \mathrm{C})$. On the other hand, the respective values for the N-H . . S S hydrogen bonds range from 3.306(3) $\AA$ (N4B-H4B . . S1D) to 3.576 (3) $\AA$ (N1B-H1B . . . S1C).

### 3.2. Hirshfeld Surface (HS) Analysis

Analysis of the possible non-covalent interactions using Hirshfeld calculations in crystalline materials gave a complete picture of the different forces which stabilize the crystal structure. All possible non-covalent interactions present in the crystal structure of 3 along with their net percentages are presented graphically in Figure 7 (blue bars). In the same figure, the percentage contributions of the interaction of all the atoms present inside the HS with an atom outside the HS (brown bars) as well as the percentage contributions of the interaction of an atom present inside the HS with all the atoms present in the surrounding area of the HS (green bars) are presented. The H . . H (39.6\%), H . . C ( $22.0 \%$ ) , $\mathrm{N} \ldots \mathrm{H}(12.8 \%)$ and $\mathrm{Br} \ldots \mathrm{H}(13.2 \%)$ contacts are the most dominant in the crystal structure of this compound. Other minor contacts such as the S . . H (3.3\%), C . . N $(3.0 \%)$, $\mathrm{Br} \ldots \mathrm{S}(2.8 \%)$ and $\mathrm{Br} \ldots \mathrm{C}(0.3 \%)$ are detected in the crystal structure of 3.

Figure 7. Intermolecular contacts and their percentages in 3. Color codes: blue (all interactions); brown (in/out) and green (out/in).

The different mapped surfaces resulting from the Hirshfeld calculations are presented in Figure 8. In the $d_{\text {norm }}$ map, the red regions are related to the $\mathrm{C} \ldots \mathrm{C}, \mathrm{C} \ldots \mathrm{H}, \mathrm{Br} \ldots \mathrm{H}$, $\mathrm{N} \ldots \mathrm{H}, \mathrm{S} \ldots \mathrm{S}$ and $\mathrm{Br} \ldots \mathrm{C}$ contacts. The short intermolecular interactions are listed in Table 6. The C3 . . C6 ( $2.367 \AA$ ), C3 . . . H13C ( $2.548 \AA$ A $)$, Br1 . . H1A ( $3.196 \AA$ A , N2 . . . H3 ( $1.849 \AA$ ), and Br1 . . C1 ( $3.470 \AA$ ) are the shortest distance non-covalent interactions.

Figure 8. Hirshfeld surfaces of 3 showing the most important interactions (A) C . . C, (B) C . . H, (C) Br $\ldots \mathrm{H}$, (D) N $\ldots \mathrm{H}$, (E) $\mathrm{S} \ldots \mathrm{S}$ and (F) Br $\ldots \mathrm{C}$.

Table 6. Short contacts in 3.

| Contact | Distance | Contact | Distance |
| :---: | :---: | :---: | :---: |
| C3 . . . C6 | 2.367 | Br1 ... H1B | 3.215 |
| C16... H13B | 2.764 | N2 ... H3 | 1.849 |
| C3 ... H13C | 2.548 | N1... H4 | 2.311 |
| $\mathrm{C} 2 \ldots . \mathrm{H} 13 \mathrm{C}$ | 2.725 | N1... H3 | 2.585 |
| Br1... C1 | 3.47 | N2 ... H13C | 2.448 |
| Br1... H1A | 3.196 | N1... H13C | 2.577 |
| S1 ... S1 | 3.286 |  |  |

The shape index and curvedness of surfaces are essential to confirm the presence of $\pi-\pi$ stacking interactions. It is clear that the red/blue triangles in the shape index and flat green area in curvedness indicated the presence of $\pi-\pi$ stacking interactions (Figure 8 ). In accord with this observation, the percentage of $\mathrm{C} \ldots \mathrm{C}$ contacts is $2.1 \%$. In addition, the decomposed fingerprint (FP) plots of all short contacts are shown in Figure 9. Without doubt, the sharp spikes in the FP plots of the majority of these contacts confirmed their importance where all have shorter distances than the vdWs radii sum of the interacting atoms (Table 6).

For 1, there are four molecules of this compound in the asymmetric formula. In this case, the $d_{\text {norm }}$ map of each molecule was calculated separately and the possible intermolecular interactions are analyzed and presented in Figures 10 and 11, respectively. The four molecules in the asymmetric unit have common types of non-covalent interactions but their percentages are slightly different in the four units.

Figure 9. Decomposed fingerprint plots for the short contacts in 3.
For 1, there are four molecules of this compound in the asymmetric formula. In this case, the $d_{\text {norm }}$ map of each molecule was calculated separately and the possible intermolecular interactions are analyzed and presented in Figures 10 and 11, respectively. The four molecules in the asymmetric unit have common types of non-covalent interactions but their percentages are slightly different in the four units.

Careful inspection of the $d_{\text {norm }}$ maps of the four units indicated the presence of a number of short non-covalent interactions which are generally shorter than the vdWs radii sum of the two atoms sharing these contacts (Table 7). These interactions which are considered important in the molecular packing of $\mathbf{1}$ are seen in the $d_{\text {norm }}$ map as red
spots. In this structure, the $\mathrm{C} \ldots \mathrm{H}, \mathrm{N} \ldots \mathrm{H}, \mathrm{S} \ldots \mathrm{H}, \mathrm{S} \ldots \mathrm{S}$, and $\mathrm{C} \ldots \mathrm{C}$ contacts are the most important.

Figure 10. Hirshfeld $d_{\text {norm }}$ surfaces for the four molecules in the asymmetric formula of $\mathbf{1}$ showing the most important interactions (A) C $\ldots$ H, (B) $\mathrm{N} \ldots \mathrm{H}$, (C) $\mathrm{S} \ldots \mathrm{H}$, (D) C $\ldots$ C and (E) S $\ldots$ S.

| S1B ... S1D | 3.137 | C5 ... C9B | 3.39 |

Decomposition of the fingerprint plots gave accurate percentages of all possible contacts in the crystal structure. It was found that, the H . . H, C . . H, N . . . H and S . . . H contacts are the most dominant in all units. Their percentages range from 34.9 to $37.4,20.5$ to $24.0,12.2$ to 13.6 and 14.0 to $15.8 \%$, respectively (Table 8 ). In addition, the sharp spikes in the decomposed fingerprint plots of these contacts indicate short distance interactions and are considered strong (Figure 12).

Table 8. Percentages of all contacts in $1^{a}$.

| Contact | A | B | C | D |
| :---: | :---: | :---: | :---: | :---: |
| S ... S | 1.1 | 0.8 | 1.1 | 0.8 |
| S... N | $1.8(1.3,0.5)$ | 1.3 (0.5,0.8) | 1.1 (0.6,0.5) | 1.4 (0.6,0.8) |
| S... C | $1.4(0.7,0.7)$ | $1.4(0.7,0.7)$ | 1.3 (0.3,0.9) | 1.3 (1.0,0.3) |
| S... H | 14.6 (9.0,5.7) | 14.5 (9.6,4.9) | 15.8 (10.0,5.8) | 14.0 (9.4,4.7) |
| N ... N | 1.1 | 1.2 | 1.2 | 1.1 |
| C... N | 3.4 (1.4,2.0) | 4.6 (2.7,1.9) | 5.8 (2.7,3.1) | 5.0 (2.8,2.2) |
| N ... H | 13.6 (7.8,5.7) | 13.3 (7.8,5.5) | $12.2(6.9,5.3)$ | 12.6 (6.9,5.7) |
| C... C | 4.1 | 4.0 | 4.5 | 4.6 |
| C... H | 22.4 (14.0,8.3) | 24.0 (12.8,11.3) | 20.5 (12.2,8.3) | 21.8 (12.5,9.3) |
| H . . . H | 36.5 | 34.9 | 36.5 | 37.4 |

${ }^{a}$ Values inside parentheses are the percentage contributions of the interaction of all the atoms present inside the HS with an atom outside the HS, and the percentage contributions of the interaction of an atom present inside the HS with all the atoms present in the surrounding area of the HS, respectively.

Figure 12. Decomposed fingerprint plots for the short contacts in 1.

## 4. Conclusions

Compound 1, 4-Amino-5-indolyl-1,2,4-triazole-3-thione, reacted with 4'-bromoacetophenone 2 in methanol and concentrated HCl to give the target compound 1,2,4-triazolo pyridazino[4,5-b]indole 3 in good yield. Crystals suitable for X-ray single crystal analysis were obtained by recrystallization from methanol. The structure of both compounds was analyzed using Hirshfeld calculations based on their accurately determined X-ray structures. While 3 crystallized in the triclinic crystal system and $P-1$ space, compound 1 crystallized in the less symmetric monoclinic crystal system and $P 2_{1}$ space group. In the former, the triazole and indole rings are twisted from each other by $12.64^{\circ}$, while the corresponding values in 1 are in the range $4.94-7.22^{\circ}$. Hirshfeld analysis indicated the significance of the $\mathrm{C} \ldots \mathrm{C}, \mathrm{C} \ldots \mathrm{H}, \mathrm{N} \ldots \mathrm{H}$ and $\mathrm{S} \ldots \mathrm{S}$ contacts in both compounds. Additionally, some short $\mathrm{Br} \ldots \mathrm{H}$ interactions were detected in 3. In both systems, the shape index and curvedness maps confirmed the presence of $\pi-\pi$ stacking interactions. Quantitative determinations of the non-covalent interactions that occurred in both crystals indicated that the $\mathrm{H} \ldots \mathrm{H}(35.3 \%), \mathrm{H} \ldots \mathrm{C}(22.5 \%), \mathrm{N} \ldots \mathrm{H}(15.4 \%)$ and $\mathrm{Br} \ldots \mathrm{H}(13.2 \%)$ contacts are the most dominant in 3 while the $\mathrm{H} \ldots \mathrm{H}(34.9$ to $37.4 \%), \mathrm{C} \ldots \mathrm{H}(20.5$ to $24.0 \%$ ), $\mathrm{N} \ldots \mathrm{H}(12.2$ to $13.6 \%)$ and $\mathrm{S} \ldots \mathrm{H}(14.0$ to $15.8 \%)$ contacts are the most abundant in 1.
