Comparison between disulfide bonds found from the atomic coordinates and from the SSBOND lines of the PDB files.

The presence of disulfide bonds was detected with two strategies, *FIND* and *GREP*.

On the one hand (*FIND* method), disulfide bonds are detected from the atomic coordinates, under the condition that the S-S covalent bond length is in the 1.9–2.1 Å range (in the case of conformational disorder, only the first conformation is considered).

On the other hand (*GREP* method), the disulfide bonds listed in the “SSBOND” lines of the PDB-formatted files are considered.

Minor differences between the results provided by the two methods are observed in 5.1% of the PDB files (from 4.8% to 5.6% amongst the 14 sets of PDB structures).

Here, a couple of examples of these discrepancies are given.

In 1fgb (cholera toxin B subunit pentamer at 2.40 Å resolution; reference A), there are five disulfide bonds, one in each protomer, between cysteines 9 and 86 (*GREP* method). However, one of them is

not detected from the analysis of the atomic coordinates since it is too long (2.14 Å; chain E), outside of the 1.9–2.1 Å range (*FIND* method).

In 1zr0 (bovine trypsin complexed by tissue factor pathway inhibitor 2 at 1.80 Å resolution; reference B), there are 17 disulfide bonds, six in chain A and in chain C (trypsin), and three in chain C and in chain D (inhibitor) (*GREP* method). However, several of them are longer than 2.1 Å—one is even 2.80 Å long—and are thus outside of the 1.9–2.1 Å range (*FIND* method).

The number of disulfide bonds found with the *FIND* methods is never larger than the number of disulfide bonds found with the *GREP* method.

Table S2. Percentages of homomeric and heteromeric intermolecular disulfide bonds found by the FIND and GREP methods in the 14 subsets of the Protein Data Bank. A homomeric disulfide bond connects two proteins that have the same amino acidic sequence; a heteromeric disulfide bond connects two proteins that have different amino acidic sequences.

Table S4. Percentages of secondary structures (ss) of the cysteines that form intra- or intermolecular DBs in the 14 subsets of the Protein Data Bank. Secondary structure assignments were performed with DSSP or Stride. DBs were identified with the FIND or the GREP methods. Only data with percentages of observations larger than 5% (in any combination DSSP/Stride or FIND/GREP) are shown.

Table S5. Average values (standard deviations of the mean in parentheses) of the solvent accessible surface area (\AA^2) of the cysteines forming intra- or intermolecular disulfide bonds in the 14 subsets of the Protein Data Bank. Disulfide bonds have been identified with the FIND and GRAP methods.

Table S6. Percentages of various types of proteins (non-enzyme and the seven types of enzymes) that contain both intra- and intermolecular disulfide bonds (Both), only intramolecular disulfide bonds (Intra-only) or only intermolecular disulfide bonds (Inter-only), in the 14 subsets of the Protein Data Bank examined in the present manuscript. Disulfide bonds are identified with the FIND or with the GREP method.
