Abstract: In this study, phenotypic variation and genetic diversity, important factors to decide germplasm for rice breeding, were evaluated among 15 rice mutants attained from the MNU (N-Nitroso-N-methylurea) mutation. The correlation coefficient values among these phenotypic characteristics were calculated. The results showed that full grain number per plant was the most relevant factor contributing to grain yield per plant, and grain length to width ratio was the key parameter affected to amylose content. Furthermore, the genetic variation among mutants was estimated by Simple Sequence Repeat (SSR) markers related to amylose content trait. Fifty-six polymorphism markers covering across eleven rice chromosomes were recorded with an average of 3.02 alleles per locus. The average value of polymorphism information content was 0.47. By using the unweighted pair group method with arithmetic mean (UPGMA) clustering, four clusters were generated with the genetic similarities ranging from 0.52 to 0.91. The variation among groups was 34%, while the variation among individuals within groups was 66%. Findings of this study provided useful genetic background and phenotypic information of collected rice mutants to breed rice cultivars with improved quality.

Keywords: phenotypic variation; genetic diversity; polymorphism information content; mutants; SSR markers; MNU (N-Nitroso-N-methylurea) mutation

1. Introduction

As an essential food for human beings, rice (Oryza sativa L.) has been widely consumed and planted around the world. Particularly, 80% of rice production in the world comes from Asian countries [1]. More than half of the world's population constantly includes rice in their diet, and about 2808 calories are provided by rice per person per day [2]. As world population growth and climate change are undeniable, demands for higher yield and better quality rice have become a critical issue [3]. Therefore, breeding new rice varieties with improved quality and productivity is an unprecedented challenge [4].

With assistance from biotechnology, rice breeding targets are not only improving crop productivity, but also upgrading quality characteristics through alterations in heredity [5]. Many tremendous efforts and rapid progresses in rice breeding programs have been carried out and received remarkable achievements [6]. As a result, new rice varieties have been developed and released with higher yield and quality.

Mutation, an effective method applied in many crops, plays a notable role in the development of desired varieties particularly in rice. Mutation may occur naturally due to alterations of base pairs in a DNA sequence [5]. These alterations can be passed from generation to generation; thus, mutation

Agriculture 2018, 8, 30 2 of 15

is the primary source of genetic variation. In accordance with recombinant breeding and transgenic breeding, mutation is currently the most effective tool of plant breeding, especially throughout sexual production [7]. As the major element of germplasm, genetic diversity is a natural source for rice breeding to encounter existing food requirements [8]. The higher the level of genetic variation is in a population, the more valuable it is as a resource is used for enlarging the genetic base in breeding program [9]. In addition, Haritha et al. [10] postulated that genetic diversity obtained precious information for both basic studies and practical applications. DNA markers have revealed a promising approach toward detecting genetic diversity and assisting in management of plant genetic resources [11]. The differentiations among accessions, individuals, and identification and characterization of novel germplasms at the molecular level, can be recognized by DNA markers and genetic engineering [12]. In association with bioinformatic tools, DNA markers provide favorably successful and reliable technologies to facilitate evaluation of genetic variation in rice. Moreover, DNA markers offer a great promise for rice breeding because of their competence and accuracy [13]. Numerous kinds of molecular markers have been practiced for calculating genetic dissimilarity in rice [14]. Remarkably, among closely related rice cultivars, SSR markers are particularly prominent for evaluation of genetic diversity as they can detect a remarkable great level of polymorphism [11,15].

Chemical mutagens have been used for genetic screens crop breeding. Compounds such as EMS (ethyl methanesulfonate) and MNU (*N*-Nitroso-*N*-methylurea)-induced single nucleotide changes by alkylation of specific nucleotides [16,17], giving mutations that were high in density and essentially randomly distributed [18]. Therefore, a relatively small population of rice can provide variety of missense changes with differing effects on protein function [19]. In a previous study, Satoh et al. [20] found that using of *N*-methyl-*N*-nitrosourea mutation caused effects to the *PHO1* gene in rice, which might play some crucial role in starch biosynthesis by forming a functional protein-protein complexed with carbohydrate metabolizing enzymes. The mutant rice lines were produced by treating fertilized egg cells of Japonica rice cultivars (*Oryza sativa* cv. Kinmaze and T65) [20], and when rice seeds mutated by MNU, the influence on the biosynthesis in rice endosperm, including amylopectin and amylose contents, has not been understood.

Rice grain quality, a persuasive factor for consumer preferences and global commerce, is a combination of physical and chemical characteristics [3]. It is categorized in different major physical and chemical indicators [6] such as appearance quality, milling quality, nutritional quality, cooking and eating quality. Amylose content (AC) is considered as one of the key characteristics for assessment of rice cooking and eating quality [21], and it may also affect some physical traits [3]. Hence, this study was conducted to evaluate the phenotypic variation of rice mutant lines achieved from MNU mutation, to determine the genetic divergence using SSR markers relevant to amylose content trait, and to investigate the alteration of rice germplasms after mutation.

2. Materials and Methods

2.1. Rice Materials

Fifteen rice mutants and four rice cultivars (all are *Indica* subtype) provided by Khai Xuan International Co. Ltd. and Agricultural Genetics Institute (Hanoi, Vietnam), respectively, were used in this study. Rice mutants were originated from cultivars, including Bao Thai, DT84, TBR1, Khang dan, SKLo, and BC15TB. To obtain rice mutants, seeds of these origin rice cultivars were soaked in 150 mM MNU (*N*-Nitroso-*N*-methylurea) for 3 h, dried, and kept in hermetic conditions before used [22]. Information of the rice materials were shown in Table 1.

Agriculture 2018, 8, 30 3 of 15

Table 1.	List of rice	materials.
----------	--------------	------------

Sample Codes	Origins	Mutants	Descriptions
В	M ₂ -Bao thai	+	Originated from Bao Thai cultivar with good quality, cold tolerance, cultivated in Northern Midland and Mountainous region in Vietnam
D	DT84	_	A traditional sticky rice with good quality in the north of Vietnam
DB_1	M ₂ -DT84/Bao thai	+	F ₂ mutant line
DB_2	M ₂ -DT84/Bao thai	+	F ₂ mutant line
DB_3	M ₂ -DT84/Bao thai	+	F ₂ mutant line
DDB_1	M ₂ -DT84DB	+	F ₂ mutant line
DDB_2	M ₂ -DT84DB	+	F ₂ mutant line
DDB_3	M ₂ -DT84DB	+	$\overline{F_2}$ mutant line
DDB_4	M ₂ -DT84DB	+	F ₂ mutant line
TK_1	M ₂ -TBR1/Khang dan	+	F ₂ mutant line
TK_2	M ₂ -TBR1/Khang dan	+	F ₂ mutant line
TK_3	M ₂ -TBR1/Khang dan	+	F ₂ mutant line
T	TBR1	_	Rice leaf blight tolerance, a high yield cultivar, extensively cultivated in Vietnam
K	Khang dan	+	High quality cultivar, broadly cultivated in the Northern and the central of Vietnam
S	SKLo	_	A high yield cultivar, widely cultivated in Vietnam
ТВ	BC15TB	_	Good quality, high yield, resistance to bacterial leaf blight and brown plant hopper, intensively cultivated in Vietnam
STB_1	M ₂ -BC15TB/SKLo	+	F ₂ mutant line
STB ₂	M ₂ -BC15TB/SKLo	+	F ₂ mutant line
STB_3	M ₂ -BC15TB/SKLo	+	F ₂ mutant line

+: Mutant; -: Cultivar.

2.2. Rice Preparation and Field Experiments

Rice seeds were soaked in 0.1% NaOCl for 30 min, and then rigorously washed several times in distilled water. These seeds were sown in Petri plates and placed at 30 $^{\circ}$ C in a plant growth chamber for two days for germination. The germinated seeds were transferred into plastic trays in a greenhouse. Two weeks-old seedlings were transplanted into the rice field. The field experiment with three replications was arranged based on randomized complete block design from May to November 2016. The area of plots was 60 m², and plant spacing was 15 \times 20 cm with one seedling per hill. Standard fertilizer was applied by hand broadcasting, and weed was managed by chemical herbicide and hand weeding. During the tilling stage until 15 days before harvesting, field water was maintained at approximately 10 cm [23].

2.3. Phenotypic Measurement

For each trait, 10 plants were randomly selected (except border plants). Grain yield characteristics consisting of panicle number per plant, panicle length, grain number per plant, 1000-grain weight, full grain number per plant, grain yield per hectare, primary branching number per panicle, secondary branching number per panicle, were recorded at the maturity stage. Panicle length was measured in centimeters from panicle base to the tip. The weight of 1000 grains was estimated based on the weight of 200 grains. Grain yield per hectare was calculated from grain yield per meter square. Grain length, grain width, and grain length to width ratio were recorded by millimeters using ten random selected grains. The grain length value was obtained by measuring the length of grain, and the grain width value was recorded based on the width of grain. The grain length to width ratio was calculated by dividing length to width [24]. Rice grains were dehusked using an Automatic Rice Husker machine (model TR-250, Kett Electric Laboratory, Tokyo, Japan), and then AC, protein content (PC), and lipid content (LC) were measured by using PGC Shizuoka Seiki PS-500 machine (version 2-12, Shizuoka Seiki Co., Ltd., Shizuoka, Japan).

2.4. DNA Extraction

The total genomic DNA of rice was extracted by cetyl-trimethyl ammonium bromide (CTAB) method [25] with some modifications. Rice young leaf (0.5 g) was cut into small pieces and placed into

Agriculture 2018, 8, 30 4 of 15

a 2.0 mL centrifuge tube with balls, and then these tubes were kept in -80 °C at least 2 h. These samples were ground into fine powder using the Tissue Lyser II machine (Qiagen, Germany). A volume of 500 µL 2% hot CTAB buffer was added into each tube and vigorously vortexed. After incubation at 65 °C for 15 min in a Block Bath Shaker (MyBL-100S, AS ONE Corp. Japan, Osaka, Japan), the suspensions were centrifuged at 12,000 rpm for 5 min at 4 °C. The supernatant was gently mixed with 250 μL of mixture chloroform: isoamyl alcohol (24:1 ratio) and left for 5 min at room temperature. After centrifugation at 12,000 rpm for 5 min at 4 °C, the supernatant was transferred to a new 1.5 mL microfuge tube, followed by added 500 μ L of isopropanol to each tube and stored at -20 °C at least 1 h. The supernatant was discarded after centrifugation at 12,000 rpm at 4 °C for 5 min, and the pellet was then washed with an amount of 500 μL 70% ethanol. The pellet was dried for 15 min at 37 °C using an Iwaki Vacuum Centrifugal Evaporator HVC 500 machine (Iwaki Co., Ltd., Tokyo, Japan). A volume of 100 µL TE (Tris-EDTA) buffer was added to each tube to dissolve the pellet. The DNA solution was kept in 4 °C (for short term storage) or -20 °C (for long term storage). The quality of DNA was checked by using 0.8% agarose gel electrophoresis for 45 min at 50 V. To visualize the DNA resolution under AMZ System Science limited STAGE system ECX-F15M (Vilber Lourmat, Eberhardzell, Germany) 2.5 µL SafeviewTM classic (Aplied Biological Materials Inc., Richmond, BC, Canada) was added to 100 mL of agarose gel.

2.5. PCR Amplification

Polymerase chain reaction (PCR) was carried out to genotype of rice mutants and their parents. Eighty-two selected SSR markers, attributed across the genome linked with amylose content QTL traits, were used to evaluate genetic diversity among rice germplasms. Primer sequences, annealing temperature and chromosomal location information were obtained from GRAMENE database [26]. PCR was performed by using Thermal Cycler GenAtlas S machine (ASTEC Co., Ltd, Fukuoka, Japan) with a total volume of 10 μ L of the mixture containing 0.5 μ L of template DNA (100 ng), 1 μ L of 10× PCR buffer, 0.8 μ L of 25 mM MgCl₂, 0.1 μ L of 1 mM dideoxynucleotides (dNTPs), 0.5 μ L of 5 μ M reverse and forward primers, and 0.05 µL of 0.5 units Taq DNA polymerase. The volume was raised up to 10 μL with deionized nuclease-free water. The PCR program was initiated by denaturation at 94 °C for 5 min followed by 35 cycles of 94 °C for 1 min, 55–65 °C (depend on annealing temperature of each primer) for 1 min and 72 °C for 2 min. A final 5 min incubation at 72 °C was allowed for the completion of primer extension. The PCR products were resolved on 5% polyacrylamide gel in $0.5 \times$ TBE (Tris-borate-EDTA) buffer at 150 V for 90 min with EZ-VISION R ONE dye as loading buffer 6× (VWR Life science, Radnor, PA, USA). The PCR product sizes were determined by a standard DNA ladder 100 bp MXL D100 Mixell (Mixell Inc., Hiroshima, Japan), and it was visualized under an ultra-violet (UV) transilluminator using AMZ System Science limited STAGE system ECX-F15M (Vilber Lourmat, Eberhardzell, Germany).

2.6. Data Analysis

The phenotypic data were analyzed by SPSS 20.0 package (SPSS Inc., Chicago, IL, USA). The contribution of each trait on amylose content was calculated using regression analysis, and the correlations among phenotypic characters were determined by Pearson correlation.

The genetic relationship among rice mutants was identified using data obtained from polymorphic markers. The amplified products of each marker were scored as 1 for the presence and 0 for the absence in a binary matrix [27]. The similarity coefficient values were used to construct a dendrogram by NTSYSpc 2.10m software (Steauket, Exeter software, New York, NY, USA), and it was carried out using method of unweighted pair group method with arithmetic mean (UPGMA) to group individuals into clusters [10].

Agriculture 2018, 8, 30 5 of 15

The heterozygosity (H) and polymorphic information content (PIC) values of a locus were calculated as described by Nagy et al. [28] with the following formula:

$$H = 1 - \sum_{i=1}^{l} P_i^2$$

where P_i is the frequency for the *i*th allele among total of *l* alleles:

$$PIC = 1 - \sum_{i=1}^{l} P_i^2 - \sum_{i=1}^{l-1} \sum_{i=n+1}^{l} 2P_i^2 P_j^2$$

where P_i and P_i are the population frequencies of the *i*th and *j*th allele.

To identify the genetic differentiation among groups and within groups, AMOVA (analysis of molecular variance) was analyzed using the data of locus by locus of each marker. The significance of estimated variance components was calculated by GenAlex software version 6.503 (Australian National University, Canberra, Australia) following 999 random permutations [29].

3. Results

3.1. Grain Yield and Yield Components

The results of grain yield measurement were presented in Table 2. These results showed a wide variation among rice mutants. Grain number per plant ranged from 815 to 3081, with the mean of 1730, and 1000-grain weight ranged from 18.10 to 25.90 g with an average of 22.35 g. The average of grain yield per hectare was 7.87 ton. The relationships between grain yield and the other traits were shown in Figure 1. Results showed that grain yield increased linear with full grain number per plant ($R^2 = 0.92$, p = 0.05), and it had a light linear with panicle number per plant ($R^2 = 0.15$, p = 0.05) and 1000-grain weight ($R^2 = 0.07$, p = 0.05) (Figure 1).

Table 2. Variability of phenotypic traits.

Characteristics	Mean	Range	SD	CV (%)
Panicle number per plant	7.23	2–12	2.24	3.22
Panicle length (cm)	24.58	19.70-29.40	2.08	11.80
Grain number per plant	1,730	815-3081	543	3.18
1000-grain weight (g)	22.35	18.10-25.90	1.90	1.90
Full grain number per plant	1,067	442-1791	306	3.48
Grain yield per hecta (ton)	7.87	2.64-15.31	2.39	3.29
Primary branching number per panicle	13.46	10–18	1.74	7.76
Secondary branching number per panicle	56.25	27-87	14.96	3.76
Grain length (mm)	5.81	4.87 - 6.52	0.48	12.10
Grain width (mm)	2.41	2.10-2.78	0.21	11.23
Grain length to width ratio (mm)	2.44	1.86 - 2.97	0.38	6.49
Amylose content (%)	22.43	17.30-24.90	2.06	10.91
Protein content (%)	6.41	1.40-11.30	2.41	2.66
Lipid content (%)	8.78	1–17	4.97	1.77

SD: Standard deviation; CV: Coefficient of variation.

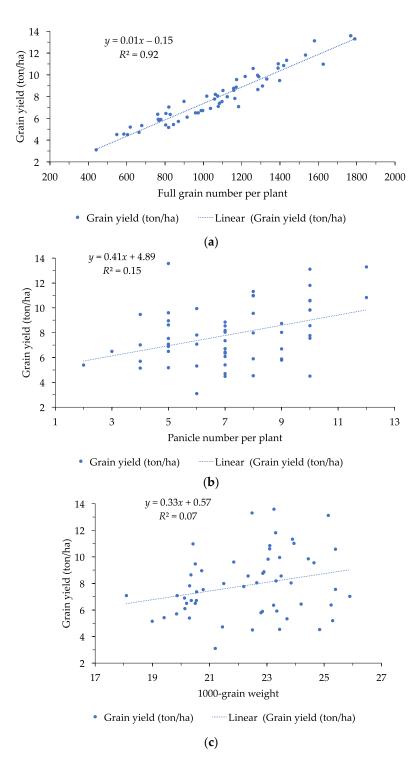

Figure 1. Relationship between grain yield and (a) full grain number per plant, (b) panicle number per plant, and (c) 1000-grain weight.

3.2. Grain Size and Chemical Quality Traits

The grain length varied from 4.87 to 6.52 mm with the mean of 5.81 mm, while grain weight ranged from 2.10 to 2.78 mm with the mean of 2.41 mm. The grain length to width ratio ranged from 1.86 to 2.97 mm with the mean of 2.44 mm (Table 2). According to IRRI (International Rice Research Institute) classification, rice mutants generally had long size (grain length > 5.5 mm, and grain length to width ratio > 2.00 mm).

Agriculture 2018, 8, 30 7 of 15

The AC ranged from 17.30% to 24.90% with mean of 22.43% (Table 2). The relationships between AC and the other traits were shown in Figure 2. Results showed that AC had a linear with grain size; in which, AC increased linearly with grain length to width ratio ($R^2 = 0.51$, p = 0.05), and it had a slight linear with grain length and grain width ($R^2 = 0.43$, and $R^2 = 0.48$, p = 0.05). Moreover, AC had no linear with PC ($R^2 = 0.00$, P = 0.05), and slight linear with LC and panicle length ($R^2 = 0.34$, $R^2 = 0.43$, $R^2 = 0.05$).

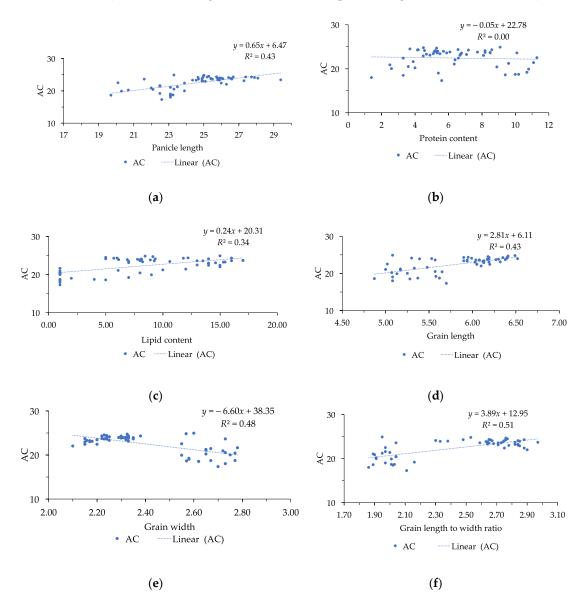

Figure 2. Relationship between amylose content and (a) panicle length, (b) protein content, (c) lipid content, (d) grain length, (e) grain width, (f) grain length to width ratio.

3.3. Correlation among Physico-Chemical Traits and Grain Yield

The correlation coefficients among phenotypic traits were shown in Table 3. The grain yield per hectare was significantly positively correlated with full grain number per plant (r = 0.96, p = 0.01), panicle number per plant (r = 0.39, p = 0.01). Grain length and grain length to width ratio had a significantly positive correlation with panicle length (r = 0.74, p = 0.01). Meanwhile, grain width had significantly negative correlation with panicle length (r = -0.67, p = 0.01), and it had significantly positively correlated with 1000-grain weight (r = 0.62, p = 0.01). Grain length and grain length to width ratio were negatively correlated with 1000-grain weight (r = -0.28, r = -0.48, p = 0.01).

The correlation between appearance quality and nutritional quality was listed in Table 3. AC had a significantly positive correlation with grain length and grain length to width ratio, whereas AC had a significantly negative correlation with grain width. The significantly positive correlation was found between AC and panicle length (r = 0.66, p = 0.01). Data in Table 3 also showed that there was a negative correlation between grain length and grain width (r = -0.72, p = 0.01), whereas grain length had an absolutely positive correlation with grain length to width ratio (r = 0.92, p = 0.01).

3.4. Genetic Diversity

A total of 82 SSR markers, randomly dispersed across on 12 chromosomes of rice, were used to evaluate the genetic diversity of the rice genotypes. Fifty-six polymorphism SSR markers distributed on 11 chromosomes of rice were detected (Table 4). A total of 167 alleles were identified, and the number of alleles ranged from 2 to 7 with an average of 3.02 alleles per locus.

Ho: observed heterozygosity per marker; H: Heterozygosity; PIC: Polymorphism information content.

Agriculture 2018, 8, 30 10 of 15

The H values ranged from 0.10 to 0.81 with an average 0.55. The PIC values varied from 0.09 to 0.79 with an average of 0.47. There were 28 highly informative markers (PIC > 0.5), 24 moderately informative markers (0.25 < PIC < 0.5) and only four slightly informative markers (PIC < 0.25). RM426 and RM431 showed the maximum PIC value and H value (0.79 and 0.81); whereas, RM60 showed the minimum PIC and H values (0.09 and 0.10). The markers RM2, RM219, RM504, RM426, RM338, RM431, RM333 showed great PIC value (0.73 < PIC < 0.79). A dendrogram constructed by UPGMA based clustering analysis divided rice mutants into four major clusters with the similarity coefficients ranging from 0.52 to 0.91 (Figure 3). Furthermore, the genetic similarity between rice mutants and their relatives was presented in Table 5.

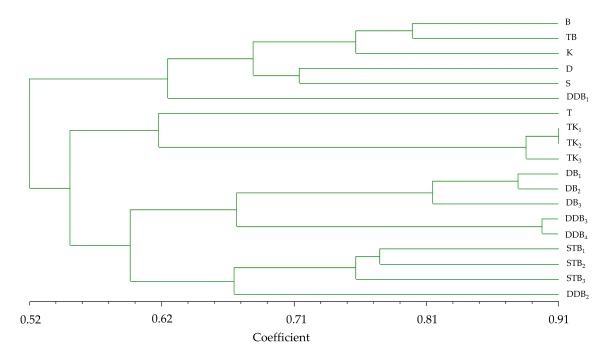

Figure 3. Cluster diagram of rice mutants and their origins.

Table 5. Genetic similarity of rice mutants and their origins.

Cluster I included six genotypes, and its similarity coefficient varied from 0.58 to 0.80. Four genotypes contributed to cluster II with the similarity coefficient from 0.58 to 0.91. The similarity

Agriculture 2018, 8, 30 11 of 15

coefficients among TK_1 , TK_2 , and TK_3 varied from 0.88 to 0.91. In which, TK_1 and TK_2 had the genetic similarity of 0.91 (the highest genetic similarity). The genetic similarity between T and TK_1 , TK_2 , and TK_3 was 0.58 to 0.63. Cluster III comprised of five genotypes originated from B, D, and mutant lines DDB_3 , DDB_4 . In this cluster, the similarity coefficient varied from 0.63 to 0.89. Four genotypes generated from S, TB, and mutant line DDB_2 grouped into cluster IV. STB_1 , STB_2 , and STB_3 were generated from S and TB; while DDB_2 has the same origin with DDB_1 , DDB_3 , and DDB_4 . The similarity coefficient of this cluster ranged from 0.63 to 0.78 (Table 5).

The AMOVA analysis revealed that there was a greatly significant genetic differentiation among groups and within groups. In which, the genetic variation was 34% among groups, whereas among individuals within groups, there was 66% of variation (Table 6).

Source	df	SS	MS	Est. Var.	%	p Value
Among groups	3	260.66	86.89	13.04	34	0.001
Within groups	15	383.55	25.57	25.57	66	0.001
Total	18	644.21		38.61	100	

Table 6. Differentiation among and within four groups of mutant genotypes by AMOVA.

AMOVA: Analysis of molecular variance; *df*: degrees of freedom; SS: sum of squares deviation; MS: mean squared deviation; Est. Var.: estimates of variance component; %: percentage of total variance contributed by each component.

4. Discussion

In this study, the rice materials were cultivated in the rice field to measure the variation in quality and yield characteristics. They were also genotyped to clarify the role of mutation. The results showed that both grain yield per plant and amylose content were varied among cultivars and mutant lines. The association among traits is a principal feature that may assist the selection of elite characteristics in breeding programs not only for rice but also for the other plants [6,30]. Discovered the role and the relationship of characteristics related to quality trait in rice is important to develop new varieties with expected quality [6]. Three main constituents of grain yield include number of panicles per plant, number of grains per panicle, and grain weight. Among them, grain weight, measured as 1000-grain weight, is a decisive trait to grain yield [12,31]. In this study, the highest significantly positive correlation was found between grain yield per plant and full grain number per plant, followed by number of panicles per plant and grain weight. This suggested that full grain number per plant has the highest contribution to grain yield, and an increase in full grain number per plant leads to an increase in grain yield.

Grain size is considered as a major determinant of grain appearance quality and grain weight, and it was contributed by grain length, grain width, and grain length to width ratio [12]. Our study agreed with many findings showed that grain weight was significantly correlated with grain size [12,31,32]. This result implied that the larger the grain, the heavier the grain. However, it is difficult for breeders to improve grain size efficiently by phenotyping, since this trait is quantitatively inherited although plants with large seed size were selected for breeding [12].

The correlation between appearance quality and nutritional quality was also found in this research. AC and protein content are two essential indicators for eating, cooking, and nutritional quality, respectively [6]. With regards to AC and grain size, our results were consistent with that previously reported by Xu et al. [33] and Abacar et al. [6]. The significant correlation between AC and grain size suggested that selection of rice mutants with high values of grain length and grain length to width ratio could result in positive response of AC. The involvement of grain length to width ratio in AC was greater than the other traits, and grain length to width ratio was the most significant character influencing AC. Therefore, rice with high grain length to width ratio leads to an increase in AC in rice [6]. Interestingly, this study also found that there was no correlation between PC and grain size. In a previous study, Lou et al. [34] stated that there was no significant correlation between AC and other quality traits.

Agriculture 2018, 8, 30 12 of 15

It was reasoned that the principal element that regulates AC was a combination of the *Wx* gene with the other minor QTLs. This finding proposed that marker-assisted selection can apply for AC. Furthermore, Abacar et al. [6] highlighted that it was difficult to explain the relationship between AC and the other traits. Additionally, Huang et al. [31] stated that there was a positive correlation between grain weight and grain size; however, the level of correlation of them was differed from independent studies.

In general, there was a dissimilarity in grain yield and AC among the rice mutants. This can be reasoned that mutation may have affected these characteristics. However, the role of mutation involving these characteristics could not be studied. Therefore, it is necessary to do further study on these traits. In the previous reports, Kumbhar et al. [27] and Salem et al. [35] stated that it is difficult to discriminate close genotypes through phenotypic assessment. Furthermore, many agronomical characteristics such as quality and yield are highly affected by environmental conditions [36]. In another report, Lo et al. [37] indicated that in normal environmental conditions, rice mutants may not exhibit desirable phenotypes; subsequently, these mutants need to be recognized by screening under appropriate or inducible conditions.

Genetic variation in a population is a worthy source for enlarging the range of genetic materials in plant breeding, and molecular markers, such as SSRs and SNPs, are effective tools to discover genetic diversity [9]. Compared to other genetic markers, SSR markers have remarkable potential to discriminate between rice genotypes [35,38]. Classification of genotypes based on polymorphism markers is a prevailing mean for assessment of genetic variance [27,38,39]. PIC value is a principal factor in distinguishing the percentage of polymorphism of a marker at a specific locus; the higher PIC value is in SSR markers, the higher percentage of polymorphism is detected [38]. In this research, most SSR markers amplified more than two alleles among all genotypes. The PIC values of the 56 polymorphism markers indicates moderate genetic diversity among rice mutants, and seven markers showed great PIC values (0.73 < PIC < 0.79). Salem et al. [35] affirmed that markers with PIC values higher than 0.7 were very high PIC values, and they can be employed to enlarge the genetic foundation of the current genotypes. In addition, SSR markers with PIC value of 0.5 or higher considered as to be effective in discriminating the polymorphism rate [10,38], and they have a potential in evaluation of genetic divergence. Therefore, when the level of polymorphism of markers was high (50% highly informative markers followed with 43% moderately informative markers), it could indicate that the rice mutants used in this study were more diverse since only the amylose content trait-based DNA marker was used. The other explanation to this might be that the rice mutants have a related origin from quality rice. In previous study, Anumpam et al. [38] found that the genetic diversity value was low when using only SSR markers related to drought trait.

The UPGMA clustering analysis delineated all 19 genotypes in four groups with difference genotypes indicating the greatness of the genetic variation among the rice mutant genotypes. Cluster I represented six mutant genotypes originated from varieties and mutant lines, and the genetic similarity of this cluster was the lowest. It was significant that these genotypes were resolved into this cluster because they were originated from different rice cultivars. Some lines were generated from a common genotype, and they obviously grouped together, such as cluster II. TK₁, TK₂, and TK₃ were originated from T and K varieties, and they grouped with T into this cluster. Interestingly, although T and K were parents of these lines, these lines clustered together with T (female parent) and separated from K (male parent); K was in cluster I, and the highest genetic similarity was found in this cluster. Although generated from a common genotype, some rice genotypes did not cluster together for instance DDB₁, DDB₂, DDB₃, and DDB₄; they clustered into different clusters while they have the same origin. Originated from D and B, DB₁, DB₂, and DB₃ were belong to cluster II; however, their parents belong to cluster I. This result was similar STB₁, STB₂, and STB₃. These results could be reasoned that, mutation may change genetic materials, and these changes lead to the genetic differentiation among rice mutants.

Agriculture 2018, 8, 30 13 of 15

Aside from alleles obtained from polymorphism SSR markers, the differentiation within groups and among groups of nineteen rice genotypes was estimated. Based on the result of UPGMA clustering method, mutant genotypes and their parents were grouped into four groups with significant divergence among group (p > 0.001). By using AMOVA analysis, high genetic diversity within groups was reveal (68%), whereas, among groups, genetic diversity was only 30%. There was a significant genetic variation among rice mutants. Mao-bai et al. [40] previously referred that it may be due to farming system alteration. This can be explained that extensive cultivation may have contributed to the occurrence of rice mutants. Although the rice mutants used in this study were selected randomly, further investigation should be conducted on the other mutant lines to understand the influence of MNU mutation on the phenotypes and genotypes correlated to amylose content in rice. Findings of this study are helpful for controlling the amylose content in rice breeding, and for widening the understanding of MNU mutation to rice quality.

5. Conclusions

In this study, variation in the phenotype and genotype of rice mutants attained from the MNU mutation has provided clues for identification of the divergence of rice mutants. It has primarily provided valuable information on the rice mutant genotypes, as well as phenotypes. This may convey the potential to select desired traits to assist for breeding programs based on the relationship among traits and genetic diversity. The findings indicate that it is possible to obtain adequate polymorphism among rice mutants from above SSR makers, and it also elucidates the positions of SSR markers in exploring the genetic diversity among mutant genotypes. Furthermore, it may also assist in choosing an effective method to improve the target traits in rice breeding by MNU mutation.

Acknowledgments: The authors thank Ministry of Agriculture and Rural Development and Ministry of Education and Training of the Socialist Republic of Vietnam, to provide Truong Thi Tu Anh a scholarship. Do Tan Khang, Nguyen Thanh Quan, and Phung Thi Tuyen are appreciated for their assistance to this research.

Author Contributions: Truong Thi Tu Anh, conducted experiments and wrote manuscript under Tran Dang Xuan instruction. Tran Dang Khanh and Tran Dang Dat prepared rice materials. Tran Dang Xuan revised and approved the final revision. All authors corrected manuscript.

Conflicts of Interest: The authors declare no conflict of interest.
