

Supplementary Materials: Distribution of Iron Oxide Core-Titanium Dioxide Shell Nanoparticles in VX2 Tumor Bearing Rabbits Introduced by Two Different Delivery Modalities

Tamer Refaat, Derek West, Samar El Achy, Vamsi Parimi, Jasmine May, Lun Xin, Kathleen R. Harris, William Liu, Michael Beau Wanzer, Lydia Finney, Evan Maxey, Stefan Vogt, Reed A. Omari, Daniele Prociassi, Andrew C. Larson, Tatjana Paunesku and Gayle E. Woloschak

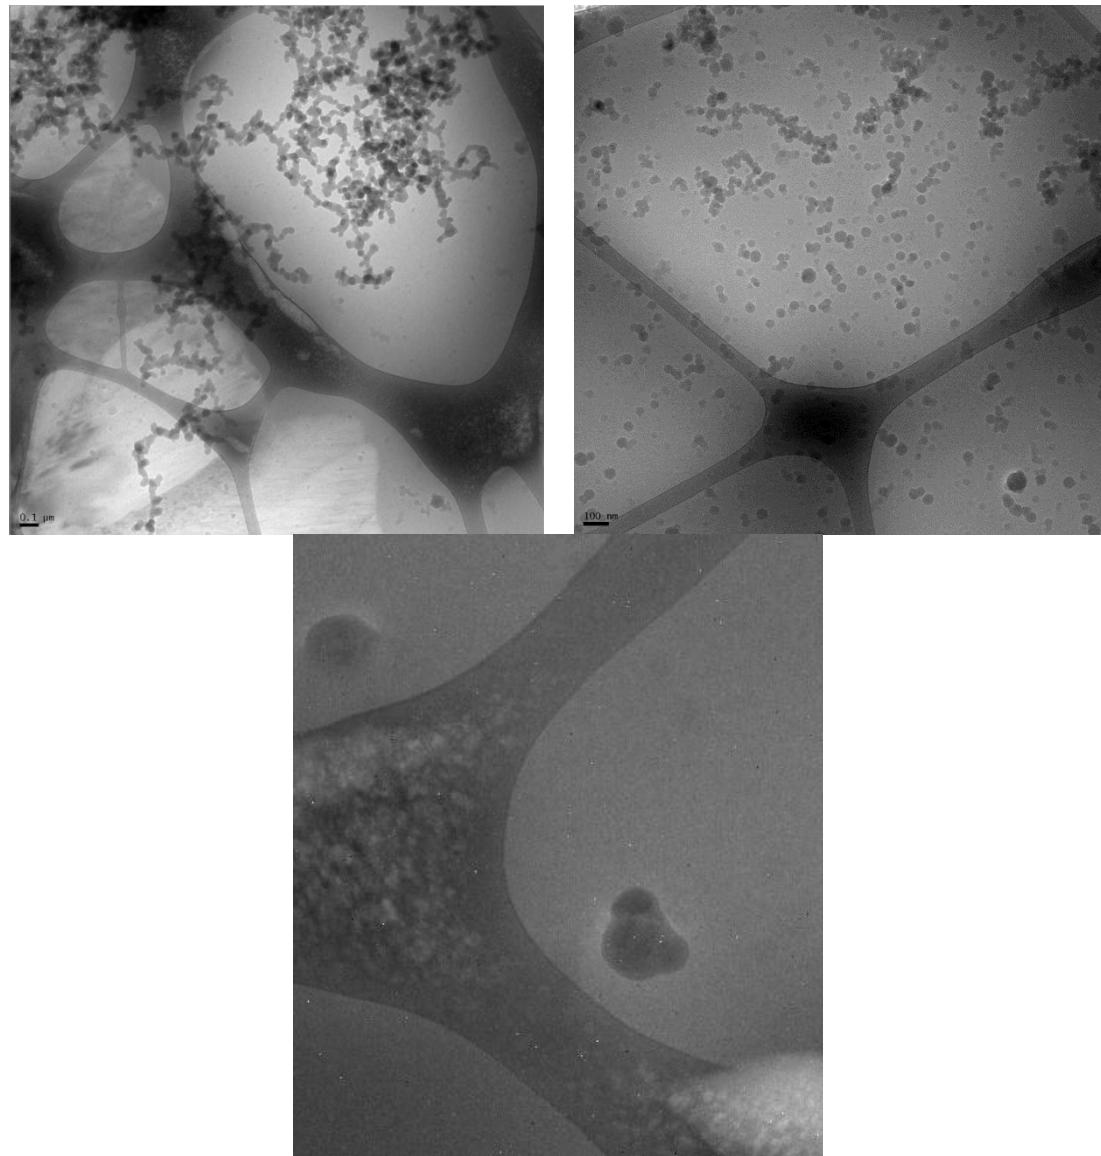

Figure S1. Cryogenic transmission electron microscopy (Cryo-TEM) of nanoparticles deposited onto and frozen on lacey carbon TEM grid at magnification: (**Top left**) 6000 \times ; and (**top right**) 8000 \times . (**Bottom Left**) Excerpt from a 10,000 \times image of the same grid. Slightly darker areas of the nanoparticle correspond to iron oxide core particles. Overall, shapes and sizes of both core nanoparticles and core-shell nanoparticles were variable. This is in keeping with results of colloidal TiO₂ synthesis we have done in the past, both for pure TiO₂ nanoparticles and for particles containing Fe₃O₄ shells [1–13].

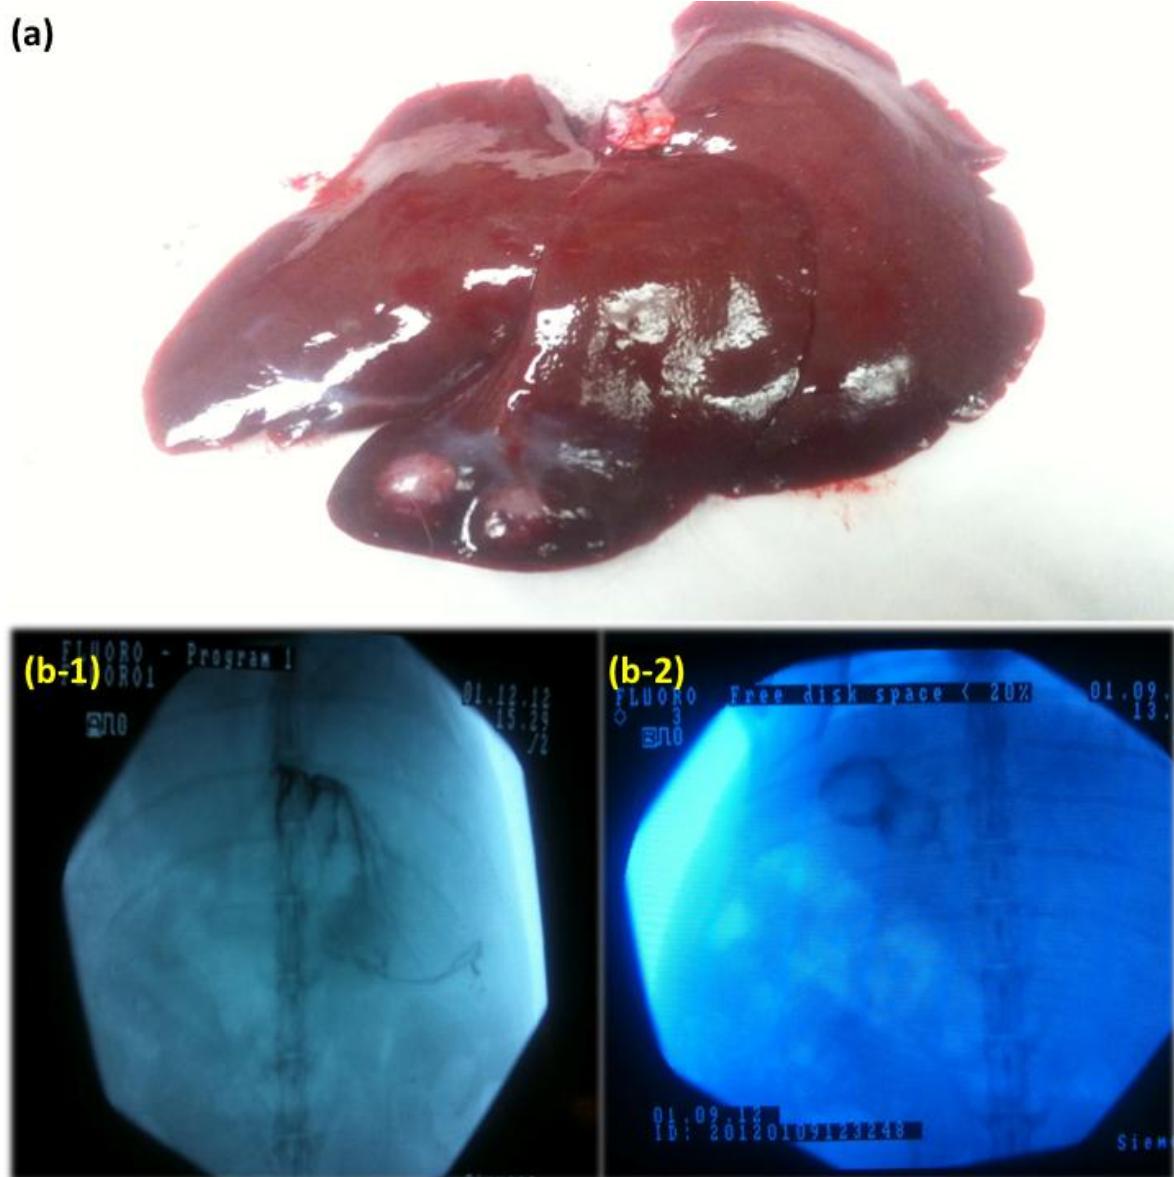

Figure S2. (a) Two VX2 tumors implanted in left lobe of rabbit liver after gross necropsy. (b) Representative selective hepatic artery X-ray DSA contrast in rabbit liver showing: hepatic artery distribution (b-1); and VX2 tumors perfusion (b-2). We have used X-Ray digital subtraction angiography (DSA) imaging to help us guide transarterial intra-catheter delivery to liver tumors as has been done in the past.
