Abstract: We report the CoII-substitution effect on a cyanido-bridged three-dimensional FeII spin-crossover network, Fe2[Nb(CN)8](4-pyridinealdoxime)8·2H2O. A series of iron–cobalt octacyanidoniobate, (FexCo1−x)2[Nb(CN)8](4-pyridinealdoxime)8·zH2O, was prepared. In this series, the behavior of FeII spin-crossover changes with the CoII concentration. As the CoII concentration increases, the transition of the spin-crossover becomes gradual and the transition temperature of the spin-crossover shifts towards a lower temperature. Additionally, this series shows magnetic phase transition at a low temperature. In particular, (Fe0.21Co0.79)2[Nb(CN)8](4-pyridinealdoxime)8·zH2O exhibits a Curie temperature of 12 K and a large coercive field of 3100 Oe.

Keywords: spin-crossover; magnetic phase transition; cyanido-bridged metal assembly; metal substitution

1. Introduction

The spin-crossover phenomenon between low-spin (LS) and high-spin (HS) states has been extensively studied in many fields [1–13]. This phenomenon can be modulated by various physical and chemical stimulations (e.g., light, pressure, temperature, vapor molecule, and metal substitution), and it has potential for sensor and memory applications [14,15]. To control the spin-crossover behavior, the metal substitution effect on the spin-crossover behavior for some FeII spin-crossover materials has been investigated [16–25].

In the field of molecule-based magnets [26–30], cyanido-bridged metal assemblies have drawn attention because they exhibit various magnetic functionalities such as a high Curie temperature (Tc) [31–34], a charge transfer transition [35–42], and an externally stimulated phase transition phenomena [43–47]. In the recent years, we have synthesized several kinds of magnetic cyanido-bridged bimetal assemblies possessing Fe spin-crossover sites. For example, CsFe[Cr(CN)6]·1.3H2O exhibits a spin-crossover phenomenon at 211 K in the cooling process (T1/2↓) and 238 K in the heating process (T1/2↑), and a ferromagnetic phase transition at 9 K [48]. Fe2[Nb(CN)8](3-pyridylmethanol)8·4.6H2O shows a gradual spin-crossover phenomenon at 250 K and a ferrimagnetic phase transition at 12 K [49]. However, the photoresponsivities were not reported for these compounds.

In 2011, we synthesized a cyanido-bridged metal assembly, Fe2[Nb(CN)8](4-pyridinealdoxime)8·2H2O, which shows a spin-crossover phenomenon at 130 K [50]. When this material is irradiated with 473-nm light, a spontaneous magnetization is observed. This photoinduced ferrimagnetic phase exhibits a TC value of 20 K and a coercive field (Hc) value of 240 Oe. This is the first demonstration of light-induced spin crossover ferrimagnetism. In 2014, we prepared Fe2[Nb(CN)8](4-bromopyridine)8·2H2O, which is the first chiral photomagnet, and observed 90° optical switching of the polarization plane of second harmonic light [51].
From the viewpoint of controlling the magnetic performance of a photomagnetic material, metal replacement is effective. In particular, Co$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·2H$_2$O, which is a metal-substituted compound of Fe$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·2H$_2$O described above as the first photoinduced spin-crossover magnet, shows a large coercive field of 15,000 Oe [52]. In this work, we synthesize cyanido-bridged metal assemblies containing both Fe and Co ions, (Fe$_{1-x}$Co$_x$)$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·2H$_2$O, and discuss the crystal structures, spectroscopic properties, and magnetic properties.

2. Results and Discussions

2.1. Syntheses

The preparation of (Fe$_{1-x}$Co$_x$)$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·2H$_2$O was performed by reacting a mixed aqueous solution of FeCl$_2$·4H$_2$O, CoCl$_2$·6H$_2$O, L-(-)-ascorbic acid, and 4-pyridinealdoxime, with an aqueous solution of K$_4$[Nb(CN)$_8$]·2H$_2$O with Fe/Co ratios [Fe]/([Fe] + [Co]) of 0, 0.1, 0.25, 0.5, 0.75, and 1, yielding a microcrystalline powder. Stirring was continued for 1 h. Then the solution was filtered and washed twice by water. Elemental analyses indicate that the chemical formula of the obtained compounds are Fe$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·3H$_2$O ($x = 0$, compound 1), (Fe$_{0.92}$Co$_{0.08}$)$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·3H$_2$O ($x = 0.08$, compound 2), (Fe$_{0.71}$Co$_{0.29}$)$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·3H$_2$O ($x = 0.29$, compound 3), (Fe$_{0.50}$Co$_{0.50}$)$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·3H$_2$O ($x = 0.50$, compound 4), (Fe$_{0.21}$Co$_{0.79}$)$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·3H$_2$O ($x = 0.79$, compound 5), and Co$_2$[Nb(CN)$_8$][4-pyridinealdoxime]$_8$·3H$_2$O ($x = 1$, compound 6). (See Section 3) The compounds of 1 and 6 in this work correspond well to the formulae in our previous reports [50,52].

2.2. Crystal Structures and Spectroscopic Properties

Table 1 and Figure 1 show the results of the Rietveld analyses of the powder X-ray diffraction (XRD) patterns for 1–6. Structural analyses show that the crystal structures of 1 and 6 are isostructural to those reported in our previous papers [50,52]. Rietveld analyses of the XRD patterns of 2–5 were performed using the crystal structure of 1 as the initial structure with the occupancies of Fe and Co based on the chemical formula. The lattice constant versus $x$ value (Co content) plot shows that the lattice constant of the $a$-axis decreases from 20.2893 Å ($x = 0$) to 20.2105 Å ($x = 1$) (0.4% decrease), while that of the $c$-axis slightly decreases from 15.0224 Å ($x = 0$) to 15.0154 Å ($x = 1$) (0.1% decrease), and the unit cell volume decreases from 6184.1 Å$^3$ ($x = 0$) to 6129.7 Å$^3$ ($x = 1$) (0.9% decrease) with increasing $x$ value (Table 1, Figure 2). It is noteworthy that the XRD peaks become broader with an increasing $x$ value. The SEM images indicate that this broadening is caused by the reduction of the crystallite size (Figure S1).

Figure 1. XRD patterns with Rietveld analyses of 1–6. Red plots, black lines, blue lines, green bars, and black bars are the observed patterns, calculated patterns, residue between the calculated and observed patterns, calculated positions of the Bragg reflections in the sample, and those of the silicon (Si) standard, respectively. The XRD peaks due to Si are shown as black sticks. Representative reflection indexes are shown in the XRD pattern of 1.
which are ascribed to the CN stretching peak due to non-bridged CN (Nb–CN) and bridged CN (Nb–CN–Co) (Figure 4). The infrared spectrum of 1 shows two CN stretching peaks at 2130 cm$^{-1}$ and 2151 cm$^{-1}$, which are ascribed to the CN stretching peak due to non-bridged CN (Nb–CN) and bridged CN between Nb and Fe (Nb–CN–Fe), respectively. In 2–6, a different peak is observed around 2160 cm$^{-1}$, and its intensity increases with an increasing Co$^{II}$ concentration, while the peak around 2151 cm$^{-1}$ decreases. This indicates that the peak around 2160 cm$^{-1}$ is due to the bridged CN between Nb and Co (Nb–CN–Co) (Figure 4).

Figure 2. $x$ dependence of (a) the $a$-axis; (b) the $c$-axis; and, (c) the unit cell volume ($V$).

The crystal structure and coordination geometries of this series are explained using 3 as an example. 3 has a tetragonal crystal structure in the $I4_1/a$ space group with $a = 20.2572(6)$ Å and $c = 15.0154(6)$ Å. The asymmetric unit is composed of a quarter of the $[\text{Nb(CN)}_8]$ anion, half of the $[\text{M}(\text{4-pyridinealdoxime})_4]$ ($\text{M} = \text{Fe or Co}$) cation, and a water molecule. Here, we assume that Fe and Co are randomly incorporated. The coordination geometries of the Nb and M sites are dodecahedron ($D_{2d}$) and pseudo-octahedron ($D_{4h}$), respectively. For the eight CN groups of $\text{Nb(CN)}_8$, four CN groups are bridged to the $M$ ions, and the other four CN groups are not bridged. Two cyanide nitrogen atoms coordinate to the two axial positions of the $M$ site and four pyridyl nitrogen atoms of 4-pyridinealdoxime are located at the other four equatorial positions. A cyanido-bridged three-dimensional (3D) network structure is formed by the $M$–NC–Nb component (Figure 3).

2.3. Magnetic Properties

Figure 5a shows the temperature dependence of the product of the magnetic susceptibility and the temperature ($\chi M T$) of 1–6 under an external magnetic field of 5000 Oe. The $\chi M T$ values of 1–6 at 300 K are 7.04, 7.08, 6.77, 6.11, 5.79, and 5.16 K·cm$^3$·mol$^{-1}$, respectively. These values agree with the estimated values of 6.96, 6.83, 6.48, 6.14, 5.79, and 5.16 K·cm$^3$·mol$^{-1}$, which are obtained by Equation (1)

$$\chi M T = \frac{N_A \mu_B^2}{3 k_B} \{2 x g_{\text{Co}}^2 S_{\text{Co}} (S_{\text{Co}} + 1) + 2(1 - x) g_{\text{Fe}}^2 S_{\text{Fe}} (S_{\text{Fe}} + 1) + S_{\text{Nb}}^2 (S_{\text{Nb}} + 1)\}$$

where $N_A$ is Avogadro’s constant, $\mu_B$ is the Bohr magneton, $k_B$ is the Boltzmann constant, $g_i$ is the $g$ value of atom $i$, $S_i$ is the spin quantum number of atom $i$, and $x$ is the Co content [53,54], assuming $g_{\text{Fe}} = 2.1, g_{\text{Co}} = 2.4, g_{\text{Nb}} = 2.0, S_{\text{Fe}} = 2, S_{\text{Co}} = 3/2$, and $S_{\text{Nb}} = 1/2$.

![Figure 5](image-url)
As the temperature decreases, the $\chi_MT$ values decreases at intermediate temperatures in 1–5, while the $\chi_MT$ value of 6 is almost constant between 50 K and 300 K. Thus, the occurrence of the Fe$^{II}$ spin-crossover phenomenon for all of the Fe$^{II}$ containing compounds is confirmed by the magnetic susceptibility measurements. The thermal spin-crossover temperature ($T_{1/2}$), which is estimated as the temperature where the temperature differential of $\chi_MT$ is maximized, shows that with an increasing $x$ value, $T_{1/2}$ shifts to a lower temperature (Figure 5b and Figure S2). In addition, with an increasing $x$ value, spin crossovers become more gradual. According to the reported observations [16–25], these results are explained as follows. Since the ionic radii of Co(II)$_{HS}$ (0.75 Å) is closer to Fe(II)$_{HS}$ (0.78 Å) than Fe(II)$_{LS}$ (0.61 Å) [55], the spin-crossover from Fe(II)$_{HS}$ to Fe(II)$_{LS}$ becomes unfavorable, leading to a decrease of the spin transition temperature. Additionally, because the distance between spin-crossover sites becomes longer by metal substitution, the cooperativity between spin-crossover sites decreases, resulting in a gradual spin-crossover behavior.

Next, we measured the magnetic properties in the low temperature region. Figure 6a shows the magnetization vs. temperature plots of 1–6 with cooling temperature at an external magnetic field of 10 Oe. The magnetization vs. temperature curves of 2 and 3 show a small shoulder below 15 K. 4, 5, and 6 clearly show spontaneous magnetization with critical temperatures ($T_c$) of 8 K, 12 K, and 18 K, respectively. The magnetization vs. external magnetic field plots at 2 K show that the magnetic coercive fields of 4, 5, and 6 are 1400 Oe, 3100 Oe, and 13,000 Oe, respectively (Figure 6b). The singleness of the $T_c$ values and the shape of magnetic hysteresis loop indicate that Fe and Co are mixed with each other on the atomic level. The observation of such a large coercive field is attributed to the single-ion anisotropy of Co ion possessing an unquenched orbital angular momentum.
Elemental analyses indicate that the chemical formulae of the obtained compounds were Fe$_2$(4 mmol), was added to an aqueous solution (2 cm$^3$) of K$_4$[Nb(CN)$_8$]·2H$_2$O (0.1 mmol) with Fe/Co ratios [Fe]/([Fe] + [Co]) of 0, 0.1, 0.25, 0.5, 0.75, and 1, yielding a microcrystalline powder. Stirring was continued for 1 h. Then the solution was filtered and washed twice by water. Elemental analyses indicate that the chemical formulae of the obtained compounds were Fe$_2$[Nb(CN)$_8$]·3H$_2$O (1), (Fe$_{0.92}$Co$_{0.08}$)$_2$[Nb(CN)$_8$](4-pyridinealdoxime)$_8$·3H$_2$O (2), (Fe$_{0.71}$Co$_{0.29}$)$_2$[Nb(CN)$_8$](4-pyridinealdoxime)$_8$·3H$_2$O (3), (Fe$_{0.50}$Co$_{0.50}$)$_2$[Nb(CN)$_8$](4-pyridinealdoxime)$_8$·3H$_2$O (4), (Fe$_{0.21}$Co$_{0.79}$)$_2$[Nb(CN)$_8$](4-pyridinealdoxime)$_8$·3H$_2$O (5), and Co$_2$[Nb(CN)$_8$](4-pyridinealdoxime)$_8$·3H$_2$O (6). 3.2. Measurements

Elemental analyses for C, H, and N were carried out by standard microanalytical methods while those for Fe, Co, and Nb were analyzed by inductive plasma mass spectroscopy. FT-IR spectra were recorded on a FT-IR4100 spectrometer (JASCO, Tokyo, Japan). X-ray powder diffraction was measured on a Ultima-IV powder diffractometer (Rigaku, Tokyo, Japan). Rietveld analyses were performed using PDXL program (Rigaku, Tokyo, Japan). Magnetic susceptibility and magnetization measurements...
were carried out using a MPMS superconducting quantum interference device (SQUID) magnetometer (Quantum Design, San Diego, CA, USA).

4. Conclusions

In this work, we synthesized and characterized ternary metal cyanido-bridged metal assemblies of \((\text{Fe}_{0.21}\text{Co}_{0.79})_{2}\text{[Nb(CN)\(_8\)](4-pyridinealdoxime)}_{8}\cdot z\text{H}_2\text{O}\). The magnetic measurements reveal that all of the Fe-containing systems present a spin-crossover phenomenon. In particular, \((\text{Fe}_{0.21}\text{Co}_{0.79})_{2}\text{[Nb(CN)\(_8\)](4-pyridinealdoxime)}_{8}\cdot z\text{H}_2\text{O}\) exhibits a coexistence of a spin-crossover phenomenon and a magnetic phase transition with \(T_c\) of 12 K and a large \(H_c\) of 3100 Oe. Additional investigations on the photomagnetic effect are in progress.
