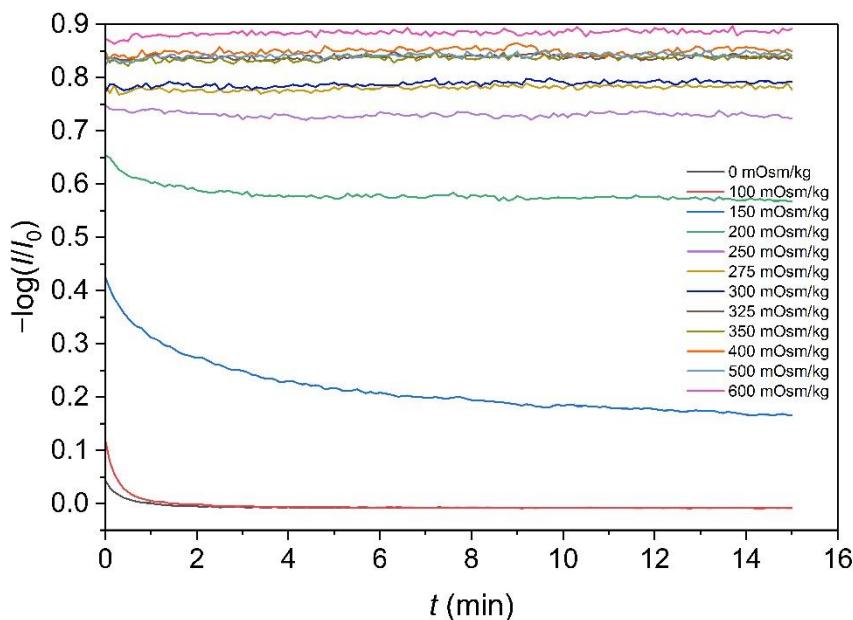

Figure S1. Kinetics of standard sodium chloride solutions. Erythrocytes lyse in 0 mOsm/kg and in 100 mOsm/kg solutions within 1 minute, as the values of $-\log(I/I_0)$ drop to 0. In 150 and 200 mOsm/kg solution, only a part of erythrocytes is lysed, since $-\log(I/I_0)$ does not reach the same low values as in the case of 0 and 100 mOsm/kg solution. $-\log(I/I_0)$ value increases with increasing osmolality, but the differences between the spectra for solutions with osmolality greater than 250 mOsm/kg are negligible and cannot set a clear boundary between isotonic and hypertonic solution.
