Part S. Calculation of r_m^2 metrics

Determination coefficient r_m^2 for the least squares regression line (without intercept) correlating observed (y-axis) and predicted (x-axis) values proposed by Roy *et al.* [1-3] was also applied to validate our QSAR models. This metric is calculated based on the correlations between the observed and predicted values with (r^2) and without (r_0^2) intercept for the least squares regression lines as shown in the following equation:

$$r_m^2 = r^2 \times (1 - \sqrt{r^2 + r_0^2}) \quad (1)$$

Average of r_m^2 and $r_m'^2$ are performed by $\overline{r_m^2} = \frac{r_m^2 + r_m'^2}{2}$ with r_m^2 is validation metric calculated according to Eq. (1) using observed (y-axis) and predicted (x-axis) values; and $r_m'^2$ is validation metric calculated according to Eq. (1) using observed (x-axis) and predicted (y-axis) values. Absolute difference between r_m^2 and $r_m'^2$ was also calculated by $r_m^2 = r_m^2 - r_m'^2$ [1-3].
