

## Supplementary Materials: Domain II of *Pseudomonas* exotoxin is critical for efficacy of bolus doses in a xenograft model of acute lymphoblastic leukemia

Fabian Müller, Tyler Cunningham, Richard Beers, Tapan K. Bera, Alan S. Wayne and Ira Pastan

**Figure S1.** Immunotoxin variants induce exposure time-dependent cell death. Indicated B-cell lymphoma cell lines were treated with 2.8 nmol/L of the Fab and the dsFv variant of WT PE24 containing immunotoxin for the indicated times, washed, and replated. Three days after assay initiation, cell viability was determined by flow cytometry. The symbols indicate the mean % of living cells at each data point of at least three independent experiments, errors are shown as SEM, curve fitting was done using 2-phase decay regression analysis using GraphPad.

**Figure S2.** Immunotoxin variants induce exposure time-dependent cell death. Indicated B-cell lymphoma cell lines were treated with 2.8 nmol/L of the Fab and the dsFv variant of the B-cell epitope depleted PE24(B) containing immunotoxin for the indicated times, washed, and replated. Three days after assay initiation, cell viability was determined by flow cytometry. The symbols indicate the mean % of living cells at each data point of at least three independent experiments, errors are shown as SEM, curve fitting was done using 2-phase decay regression analysis using GraphPad.

**Supplementary Table S1.** IC<sub>50</sub> pM for growth inhibition by WST8 assays.

Shown are all cell lines from Figure 2 in alphabetical order. The time, cells had to be exposed was determined experimentally and analyzed with a two-phase regression model. Thus, two half-lives are determined as fast and slow for the respective immunotoxin.
