

Supplementary Information

Table S1. Scores reflecting the changes for human pressure indicators.

| Human Pressure | Indicator | Data Used in This Study (Period) | Classes (Acronyms) | Score | References for Indicators and Classes |
|---|--|----------------------------------|--------------------|---|---|
| On longitudinal continuity upstream, on the basin scale | Basin area upstream dams and reservoirs | Other published studies [1,2] | 0 | 0 | [3] |
| | | | 0%–33% | 3 | |
| | | | 33%–66% | 6 | |
| | | | >66% | 9 | |
| | Other interventions on river longitudinal continuity upstream (e.g., weirs, check dams, bridges) | | Absent (A) | 0 | We extended the analysis of these indicators from local scale to catchment scale based also on [3]. |
| | | | Moderate (M) | 3 | |
| On longitudinal continuity, on the local scale | Number of local weirs or check dams on sector length | Orthophotos (2010) | Intense (I) | 6 | |
| | | | 0 | 0 | |
| | | | <1/1 km | 4 | |
| | Number of local bridges on sector length | | >1/1 km | 6 | |
| | | | 0 | 0 | |
| | | | <1/1 km | 2 | |
| On lateral continuity, on the local scale | Length of bank protection from both banks length | >1/1 km | 3 | Bravard <i>et al.</i> [4] consider that forestation favored the lateral stability of river channel. | |
| | | <5% | 0 | | |
| | | 5%–33% | 3 | | |
| | Length of reforested banks from both banks length | >33% | 6 | | |
| | | <5% | 0 | | |
| | | 5%–33% | 2 | | |
| Length of levees (close or at the contact) from both banks length | >33% | 3 | [3] | | |
| | <10% | 0 | | | |
| | 10%–50% | 3 | | | |
| On the substrate | Length of quasi-impermeable revetments on sector length | >50% | | 6 | |
| | | 0 | | 0 | |
| | | <1/1 km | | 3 | |
| | Length of rectifications from sector length | >1/1 km | 6 | | |
| | | 0 | 0 | | |
| | | <10% | 2 | | |
| Various impacts | Local sediment mining activity (in-stream, from the floodplain) | >10% | 3 | [3] | |
| | | Intense (I) | 6 | | |
| | | Moderate (M) | 3 | | |
| | Wood removal | Absent (A) | 0 | | |
| | | Moderate (M) | 2 | | |
| | | Intense (I) | 5 | | |
| Removal of riparian vegetation | Field surveys | Absent (A) | 0 | | |
| | Moderate (M) | 2 | | | |
| | Intense (I) | 5 | | | |

Table S2. Scores of change/trend for channel form indicators.

| Channel Adjustments | Indicator | Data Used in This Study (Period) | Classes | Score | References for Indicators and Classes |
|-------------------------|--|--|----------------|-------|--|
| Longitudinal Lateral | Wavelength Streamwise length Sinuosity index Amplitude Radius of curvature (r_c) Width (w) r_c/w | Topographic maps (1954) & Orthophotos (2005) | No change (NC) | 0 | Meanders' geometry parameters are calculated based on the scheme of Leopold <i>et al.</i> [5]. The change in meander geometry for 1954 and 2005 time horizons was compared with Mann-Whitney non-parametric test [6]. |
| | | | Change (C) | 6 | |
| Vertical | Cross-sectional area Maximum depth Width-to-mean-depth ratio | Cross profiles (1966–2010) | Trend (T) | 0 | Cross-section area was previously used by Salit [7], maximum depth by James [8] and width-to-mean-depth ratio by Rasmussen and Mossa [9]. We evaluated the trend of area, maximum depth and width-to-mean-depth ratio time series for 1966–2010 by using non-parametric test of Mann-Kendall [10]. |
| | | | No trend (NT) | 6 | |

Table S3. Scores of change for functionality indicators.

| Functionality | Indicator | Data Used in This Study (Period) | Classes (Acronyms) | Score | References for Indicators and Classes | |
|------------------------------|--|--|--|---------|--|------|
| Within the valley | Presence of a continuous and large floodplain from both banks length | Orthophotos (2010) | >66% | 0 | [11] | |
| | | | 10%–66% | 3 | | |
| | | | <10% | 5 | | |
| | Connectivity between terraces and river corridor from both banks length | | >90% | 0 | | |
| | | | 33%–90% | 3 | | |
| | | | <33% | 5 | | |
| Within the erodible corridor | Intensity of lateral migration of meanders | Topographic maps (1954) & Orthophotos (2005) | Intense (I) | 0 | Lateral migration of meanders is compared with the types proposed by Hooke [12]. | |
| | | | Moderate (M) | 2 | | |
| | | | Absent (A) | 5 | | |
| | Intensity of cut-off process before and after 1954 | Other published studies [2] | Same or more intense (>I) | 0 | | |
| | | | Less intense (<I) | 6 | | |
| | Presence of accumulation forms (<i>i.e.</i> , above-water bars devoid of vegetation in the vicinity of convex banks of analyzed meanders) | Orthophotos (2010) | Intense (I) | 0 | | [11] |
| | | | Moderate (M) | 2 | | |
| | | | Absent (A) | 3 | | |
| | | | Length of a potentially erodible corridor from both banks length | >66% | 0 | |
| | | | | 33%–66% | 3 | |
| | | | | <33% | 6 | |

Table S3. Cont.

| Functionality | Indicator | Data Used in This Study (Period) | Classes (Acronyms) | Score | References for Indicators and Classes |
|----------------------------------|---|--|---|-------|--|
| Within the river channel | Composition of the substrate | Cross-sectional profiles (1966–2010) | No change (NC) | 0 | [11] |
| | | | Change to a similar grain size particles (~C) | 2 | |
| | | | Change (C) | 5 | |
| | Presence of large wood in-stream | Field surveys | Present (P) | 0 | |
| Absent (A) | | | 3 | | |
| Connectivity with the floodplain | Presence of oxbow wetlands | Orthophotos (2005) | Present (P) | 0 | The return period of Q_b was estimated based on Log-Pearson III distribution; this distribution is derived from three-parameter gamma distributions by logarithmic transformation and is a popular choice for fitting the frequency distribution of extreme hydrologic data such as annual flood data [6]. Q_b with a return interval of 1–2 years is considered normal by Leopold [13]; 50 years is the life span of levees [14]. |
| | | | Absent (A) | 6 | |
| | Return period of bankfull discharge (Q_b) | Cross profiles (1966–2010) & Maximum annual discharges (1961–2010) | 1–2 years | 0 | |
| | | | 2–50 years | 3 | |
| | | | >50 years | 6 | |
| | Frequency of geomorphologically efficient floods (Q_{10}) | Maximum annual discharges (1961–2010) | Several times | 0 | |
| One time | | | 3 | | |
| Never | | | 6 | | |

Scores for pressure and alteration indicators on the Lower Prahova River

Indicators of pressures

- Basin area upstream dams and reservoirs—score = 6. We took into account six dams (Figure 1c), with or without reservoirs; according to data from Aquaproiect [1] they account for 34% of Prahova basin area.
- Other interventions on river longitudinal continuity upstream (e.g., weirs, check dams, bridges)—score = 3. We counted 41 bridges crossing Prahova River upstream the analyzed sector. Previous studies [2] showed several examples of weirs located downstream bridges in order to protect them from channel incision. Taking into account their number and roles, we estimated a moderate impact of these interventions on fluvial dynamics.
- Number of local weirs or check dams on sector length—score = 0. Absence of investigated elements.
- Number of local bridges on sector length—score = 2. We counted 8 bridges crossing the analyzed sector (length = 90 km), accounting for a density of 0.09 bridges/km.

- Length of bank protection from both banks length—score = 0. Absence of investigated elements.
- Length of reforested banks from both banks length—score = 2. We calculated a length of reforested banks of 27% of both banks.
- Length of levees (close or at the contact) from both banks length—score = 0. We calculated a length of levees for defense against flooding of 2.6% of both banks.
- Length of quasi-impermeable revetments on reach length—score = 0. Absence of investigated elements.
- Length of rectifications from reach length—score = 0. Absence of investigated elements.
- Local sediment mining activity (in-stream, from the floodplain)—score = 0. Absence of investigated elements.
- Wood removal—score = 0. Absence of investigated elements.
- Removal of riparian vegetation—score = 0. Absence of investigated elements.

Indicators of alteration: channel adjustments

- Wavelength—score = 0. Mann-Whitney two-tailed test detected no statistically significant changes between 1954 and 2005.
- Streamwise length—score = 0. Mann-Whitney two-tailed test detected no statistically significant changes between 1954 and 2005.
- Sinuosity index—score = 0. Mann-Whitney two-tailed test detected no statistically significant changes between 1954 and 2005.
- Amplitude—score = 0. Mann-Whitney two-tailed test detected no statistically significant changes between 1954 and 2005.
- Radius of curvature (r_c)—score = 6. Mann-Whitney two-tailed test detected statistically significant changes between 1954 and 2005. Mann-Whitney upper-tailed test indicated lower values in 2005 when compared to 1954.
- Width (w)—score = 6. Mann-Whitney two-tailed test detected statistically significant changes between 1954 and 2005. Mann-Whitney upper-tailed test indicated lower values in 2005 when compared to 1954.
- r_c/w —score = 0. Mann-Whitney two-tailed test detected no statistically significant changes between 1954 and 2005.
- Cross-sectional area—score = 0. Mann-Kendall two-tailed test detected no statistically significant trend in data series from 1966–2010.
- Maximum depth—score = 0. Mann-Kendall two-tailed test detected no statistically significant trend in data series from 1966–2010.
- Width-to-mean-depth ratio—score = 6. Mann-Kendall two-tailed test detected a statistically significant trend in data series from 1966–2010. Mann-Kendall lower-tailed test indicated a decreasing trend in data series from 1966–2010.

Indicators of alteration: functionality

- Presence of a continuous and large floodplain from both river banks—score = 0. We considered that the Lower Prahova River crosses a lowland, therefore, we assumed that it crosses a continuous and large floodplain.

- Connectivity between terraces and river corridor from both banks length—score = 0. We considered Lower Prahova River to be connected with the terraces on 97.4% from both banks (except for levees for protection against floods).
- Intensity of lateral migration of meanders—score = 2. We considered the presence of one rotation and one extension processes between 1954 and 2005 as a moderate intensity of lateral migration of meanders.
- Intensity of cut-off process before and after 1954—score = 6. We considered the cut-off process as being less intense after 1954, because 2 cuts-off happened between 1954 and 2005 compared to 12 cuts-off between 1900 and 1954 (Table S4).
- Presence of erosion and accumulation processes in the river channel—score = 2. We counted 14 examples of accumulating convex banks with bars devoid of vegetation among 52 analyzed meanders, which we classified as moderate intensity of meandering process.
- Length of a potentially erodible corridor from both banks length—score = 0. We estimated the length of the potentially erodible corridor as corresponding to 70.4% from both banks (except for reforested banks and levees for defense against flooding).
- Composition of the substrate—score = 2. We noticed on cross-sectional profiles that grain-size diminished from gravel and sand before 1995 to only sand exclusively after 1995.
- Presence of large wood in-stream—score = 0. We recorded occasionally presence of trunks and branches.
- Presence of oxbow wetlands—score = 2. We determined that all the oxbow wetlands present in 1954 were still functioning in 2005.
- Return period of bankfull discharge (Q_b)—score = 3. We estimated Q_b at 278 m³/s and the return period at 2.8 years.
- Frequency of geomorphologically efficient floods (Q_{10})—score = 0. We estimated Q_{10} at 550 m³/s and we counted five geomorphologically efficient floods during the analyzed time horizon (in 1966, 1972, 1975, 1997, and 2005).

Table S4. Cut-off of meanders during 1900–2005 time horizon.

| Year | Number of Meanders | Period | Number of Cuts-Off |
|------|--------------------|-----------|--------------------|
| 1900 | 52 | 1900–1954 | 12 [2] |
| 1954 | 53 | | |
| 2005 | 52 | 1954–2005 | 2 |
