1 Introduction

This appendix provides supporting information for the manuscript entitled "Systems vaccinology for a live attenuated tularemia vaccine reveals unique transcriptional signatures that predict humoral and cellular immune responses".

2 Supplemental methods

2.1 Study Design

This laboratory substudy was a systems biology study of the human response to two lots of tularemia vaccines assessed in a phase 2 clinical trial [1]. Tularemia is caused by *Francisella tularensis*, a gram-negative bacterium that has been weaponized as an aerosol. For protection of personnel conducting biodefense research, the United States Army required clinical evaluation of a new lot of tularemia live vaccine strain manufactured in accordance with Current Good Manufacturing Processes. To assess this, a phase 2 randomized clinical trial was conducted comparing the new lot (DVC-LVS) produced by DynPort Vaccine Company to the existing vaccine that has been in use by the United States Army Medical Research Institute of Infectious Diseases (USAMRIID-LVS) for decades. The vaccines were delivered by scarification to 228 participants in the main study, which evaluated vaccine safety, reactogenicity, take and Tularemia-specific microagglutination titer on Days 0 (baseline), 8, 14, 28, 56, and 180. For this substudy, blood samples were obtained for 42 healthy male and female subjects aged 18 to 45 years old, enrolled in [1]. Laboratory assessments on Days 0, 1, 2, 7, and 14 included gene expression based on PBMC RNA using microarrays, serum cytokine/chemokine concentration measurements, and immune cell phenotyping (DC/monocyte/lymphocyte cells). T-cell activation was evaluated on Days 0, 14, 28, 56, and 180. Day 180 also included an assessment of T-cell proliferation.

2.2 Microarray experiment

Affymetrix High-throughput (HT) Perfect Match (PM) Array GeneChips were run in a 96 array plate configuration (96 samples per HT array). Each individual array contained 54,715 probe sets and 536,460 perfect match (PM) probes (on average 9.8 probes per probe set). HT PM Array Plates only contain PM probes. Mismatch probes (MM) are not included. Three 96 HT array plates were run producing data for 205 samples (the last 96 HT array contained data for 13 samples). Plates were run on three different days (10/11/2011, 11/8/2011, and 11/15/2011). For five samples array data was not produced: subject T02HC051 was missing Day 1; T02HC115 was missing Days 2, 7, and 14; T02HC118 was missing Day 0. All of the other 39 subjects had array data for all 5 time points (Day 0, 1, 2, 7, 14).

2.3 Cell mediated immunity experiments

Phenotyping of immune cell subpopulations This assay included 3 panels. It was performed pre-vaccination (Day 0), and at Days 1, 2, 7 and 14 post-vaccination. Results were measured in percent live PBMCs as well as mean fluorescence intensity.

For the dendritic cell panel, samples were first gated to exclude dead cells, debris, and doublets. Total Dendritic cells (DCs) were then defined as lineage negative (CD3-CD14-CD16-CD19-CD20-CD56-) and HLADR+. DCs were then divided into myeloid dendritic cells (mDCs) and plasmacytoid dendritic cells (pDCs) subset based on CD11c and CD123 expression, respectively. mDCs were then further subdivided based on BDCA1 expression. All populations were then analyzed for CCR7, CD86, CD11b, and HLADR expression.

For the monocyte panel, samples were first gated to exclude dead cells, debris, and doublets and then B-cells and T-cells were excluded by CD19 and CD3 expression. HLADR+ cells were then defined as monocytes. Monocytes were then subdivided into CD14+ CD16- classical monocytes, CD14+ CD16+ intermediate monocytes, and CD14 dim CD16+ non-classical monocytes. All populations were then analyzed for CD86, CCR5, and HLADR expression.

For the lymphocyte panel, samples were first gated to exclude dead cells, debris, and doublets. CD14+ cells are excluded and CD14- cells were divided into CD3+ (T cells), CD19+ (B cells), and CD3- CD19- subsets. CD3+ cells were then divided into CD4+ and CD4- subsets and further analyzed for HLADR expression. The CD3-CD19- population was divided into CD56 bright (CD56 high CD16-) and CD56 dim (CD56 mid CD16+) natural killer (NK) cell subsets. All populations were then analyzed for CCR5 and CD69 expression. Expression of CCR7, CD86, CD11b, HLADR, CCR5 and CD69 was reported as mean fluorescence intensity (MFI). Background fluorescence was subtracted using isotype controls for all antibodies but anti HLADR.

T-Cell activation by phenotyping Phenotyping of T-cell activation was performed with whole blood samples at Day 0 (baseline), and Days 1, 2, 7, 14, 28 and 56 post-vaccination. Lymphocytes were identified based on forward scatter (FSC) and side scatter (SSC) properties. CD3+CD4+CD8- cells and CD3+CD4-CD8+ cells were defined as CD4 and CD8 T-cells. Activated T-cells were defined by co-expression of CD38 and HLA-DR (surface staining) or co-expression of Ki67 and Bcl-2 (intracellular staining) separately. Results were measured in percent live PBMCs.

T-cell proliferation assay The CFSE proliferation assay was performed using PBMCs from participants at Day 180 post-vaccination. Cells were labeled with CFSE and stimulated for 6 days with formalin-inactivated Tularemia Type B strain LVS or Type A strain SCHU S4 and then analyzed by

FACS. Lymphocytes, CD4 and CD8 T-cells were gated as described above. T-cell proliferation potential was determined as percent of CFSE low cells on CD4 and CD8 T cells separately and was normalized by subtracting percent of CFSE low cells obtained for negative (unstimulated) controls.

Serum cytokines/chemokines Human plasma cytokines were analyzed for Days 0, 1, 2, 7 and 14 using the Bio-Plex Pro Human Cytokine 27-plex Assay (Bio-Rad) according to manufacturer's instruction and are represented as pg/ml.

2.4 Microarray data preprocessing

Probe set annotations for HT HG-U133 Plus PM GeneChips were downloaded from the Affymetrix website (Release 34, 10/23/13). Due to missing MM probes, MAS 5.0-based average background and scale factors could not be calculated as outlined in the SAP. Instead, a median scaling factor for each sample was calculated by first calculating a scaling factor for each probe on the \log_2 scale (median across all samples divided by probe intensity) followed by calculating the median of all probe scaling factors per sample. High values indicate that a library had typically lower probe values and vice versa. RNA quality and transcript truncation was evaluated by using β -actin and GAPDH housekeeping control probe sets that target different regions of the same gene (3' end of transcript, middle (M) portion of the transcript, and 5' end of transcript). 3'/5' ratios and M/5' ratios were calculated for each individual array. Hybridization and overall signal quality for each array was evaluated using 4 Affymetrix spike-in probe sets (BioB, BioC, BioD, CreX) that are added to the experiment with increasing RNA concentrations (as listed from low to high). Median intensity was used to summarize intensities per probe set and \log_2 value of the ratio was reported. The slope (proxy for hybridization strength) was estimated for each sample by fitting a linear regression model. RNA-degradation was inspected by plotting average probe intensities in the 5' to 3' direction (the first 8 probes were included per probe set). The RNA degradation slope was estimated for each sample by fitting a linear regression model. The Robust Multichip Average (RMA) algorithm (Irizarry *et al.*, 2003) was used to obtain background-corrected and quantile-normalized probe-level intensities. Probe and probe-level \log_2 intensity distributions were investigated using boxplots, probability density function (PDF) plots, and log expression (RLE) boxplots (Brettschneider *et al.*, 2008). The ComBat algorithm [2] using the parametric empirical Bayes option was applied to adjust the probe-level data for batch effects. Extreme outliers were removed from the probe level data and background correction, quantile normalization, and batch correction was rerun in the specified order. Next, probe sets with a sample coefficient of variation ($\hat{CV} = \frac{s}{\bar{x}}$) in the lower 25% quantile were filtered out.

2.5 Differential gene analysis

A two-sided paired t-test was applied to identify significantly up/down-regulated genes from baseline (Day 0 versus Day 1, 2, 7, 14). The paired test was carried out separately for each study group as well as for combined study groups. In addition, \log_2 fold changes per study visit were compared between study groups using a two-sided Welch's t-test. To compensate for multiple testing, the false discovery rate (FDR) which controls the false positive rate among significantly differentially expressed genes was calculated using the *qvalue* R package. Genes with a q-value ≤ 0.05 and a fold change of ≥ 1.5 -fold (up or down regulation) were deemed to be significantly differentially expressed.

2.6 Determination of robust gene clusters

\log_2 fold changes of genes that were differentially expressed for a certain study group at any post baseline day were used as input for gene clustering. Uncentered Pearson correlation distance was used as distance measure. Pairwise distances between \log_2 changes were calculated separately for each vaccine group and post baseline day (Day 1, 2, 7, 14) as well as for all study days (Day 1-14). Clusters were obtained using the hierarchical complete linkage clustering algorithm. To evaluate robustness of gene clusters, multiscale bootstrapping (Suzuki and Shimodaira, 2006) was carried out using varying dataset sizes (0.4*N, 0.5*N, 0.6*N, 0.7*N, 0.8*N, 0.9*N, 1*N, 1.1*N, 1.2*N, 1.3*N; where N stands for the respective dataset size). For each dataset size bin, 1,000 bootstrap samples were obtained, and bootstrap probabilities and p-values were calculated. The unbiased bootstrap probability cut-off was set to 0.05 and the maximum distance to form a significant cluster was set to 0.5 (equivalent to minimum uncentered Pearson correlation of 0.5). Clusters that were formed at larger distances were excluded.

2.7 Gene set enrichment analysis

Gene set enrichment analysis was performed using the Java implementation (Version 2.1.0, downloaded 01/23/2015 from <http://www.broadinstitute.org/gsea>) of the GSEA algorithm (GSEAPreranked method) to detect enriched gene sets [3]. Ensemble genes were grouped and analyzed based on 8,101 known gene sets obtained from the KEGG database (Version 70.0 (06/09/2014), [4]) and MSigDB (Version 4.0 (05/31/2013), [5]). The MSigDB gene set collection was comprised of GO Biological Processes, GO Cellular Components, GO Molecular Functions, Reactome Pathway, BioCarta Pathway, Chemical/Genetic Perturbations, and Immunologic Signature gene sets. GSEA analysis was carried out separately for each post-vaccination day, comparison group (post-vaccination vs. baseline for DVC-LVS, post-vaccination vs. baseline for USAMRIID-LVS, and post-vaccination vs. baseline for the combined groups, as well as DVC-LVS vs. USAMRIID-LVS for each post-vaccination day). Probe set IDs were converted to Ensembl gene IDs based on Affymetrix HG U133 release 34 probe set annotations. To increase annotation coverage, for genes that did not have Affymetrix Ensembl gene IDs assignments,

if available, common name to gene ID mappings were obtained from the HUGO Gene Nomenclature Committee (www.genenames.org, downloaded 05/12/2015). Ranked lists of Ensembl gene IDs based on decreasing t-statistic were used as input for Chemical/Genetic Perturbations, and Immunologic Signature gene. For all other gene set collections, the absolute t-statistic was used. In either case, before generating the lists, the largest absolute t-statistic was used for Ensembl gene IDs that mapped to multiple probe sets. Except for Chemical/Genetic Perturbations, and Immunologic Signature gene sets which contain directional information, the absolute t-statistic was used. Program specifications were as follows: random seed was specified as 149, collapse was set to false, the minimum and maximum gene set size was not restricted (set to 1 and 10000, respectively), and the number of permutations was set to 10,000. To adjust for testing multiple gene sets per category type, the Benjamini-Hochberg procedure was applied to each list. For Chemical/Genetic Perturbation and Immunologic Signature collections, with many more gene sets compared to the other gene set collections, a FDR < 0.01 was applied to determine significant enrichment. For all other collections, a cut off of FDR < 0.1 was used. Enrichment trends across post-vaccination days and comparison groups were visualized using heatmaps and binary Jaccard-distance based complete-linkage hierarchical clustering.

2.8 Regularized logistic regression analysis

As there is no *a priori* knowledge about the correlates of protection for these vaccines, responders, non-responders, and subjects with high baseline were arbitrarily defined. The positive cut off for immune response thresholds for responders based on the percentage of activated CD4+, CD8+ T-cells and microagglutination titer was defined as three standard deviations (SD) above the mean of all baseline samples. Concurrently, a minimum sample size of 10 subjects in either response group (responders and non-responders) was required. The minimum subject criterion was met for responders and non-responders when combining vaccine study arms based on CD8+ T-cell activation and microagglutination titer but not for percent activated CD4+ T-cells. As the SAP allowed for flexibility in the choice of the cut off, the numbers of responders and non-responders in the combined data set were plotted for different SD cut offs to see if an alternative cut off can be identified that meets the minimum subject requirement. Based on the CD4+ plot, a cut off of 2 SD was chosen to define a positive CD4+ response. The classification for subjects with persistent T-cell responses (3 SD above the baseline mean at Day 7, 14, and 28) versus transient T-cell responses (3 SD above the baseline mean at Day 7 and 14 but below this cut off at Day 28) did not meet the minimum number of required subjects for CD4+ and CD8+ for any SD cut off. Thus, the comparison of transient versus persistent subjects was not carried out. The following criteria were used to define assay-specific responders and non-responders:

1. classification based on Tularemia-specific microagglutination titer
 - (a) responder: a subject in which tularemia vaccine induces an increase in Tularemia-specific log-transformed microagglutination titer that is 3 SD above the mean of all log-transformed baseline values, at any of the following time points: Days 14 or 28.

- (b) non-responder: a subject in which tularemia vaccine does not induce an increase in tularemia specific log-transformed microagglutination titer that is 3 SD above the mean of all log-transformed baseline values, at any of the following time points: Days 14 or 28.
- (c) subject with high baseline: a subject with a log-transformed baseline value that is 3 SD above the mean of all log-transformed baseline values.

For each post-vaccination Day (1, 2, 7, 14) and assay-specific classification, a regularized logistic regression model was fit to identify gene responses that distinguish between responders and non responders using the *glmnet* R package (Version 2.0-2). Before fitting the models, the predictor variable set (probe sets) was processed as follows:

1. probe sets corresponding to the same gene (same gene name) were collapsed by retaining the probe set per gene that had the highest absolute mean fold change from baseline at the respective post vaccination-day.
2. collapsed probe sets with an absolute fold change ≥ 1.5 were retained and used as predictors for the respective model.

To avoid overfitting ($n \ll p$ and collinearity among gene responses) and facilitate variable selection, an elastic net regularization step (combination of L1 Lasso and L2 ridge penalization, $\alpha = 0.5$) was included as part of the fitting procedure. Five-fold cross validation was used to determine the optimum regularization parameter λ based on the minimum average model deviance across folds. In addition, the mean misclassification error across folds was determined for the optimal λ and provided as additional cross-validation statistic. The five random folds were stratified by positive and negative responders, i.e. the overall proportion of positive/negative responders was maintained for each random fold. The seed was set to 20151121.

2.9 Regularized canonical correlation analysis

To identify patterns that explain associations between changes in gene expression and peak changes in immunogenicity outcomes (IMO), multivariate regularized Canonical Correlation Analysis (CCA) was carried out separately for Days 1, 2, 7, and 14. CCA identifies linear combinations of the original variables (referred to as canonical variates) that maximize the inter-set correlation (here gene and immunogenicity variable sets). Planned immunogenicity variables included peak baseline fold change in %T-cell activation (CD8+ and CD4+ cells), T-cell proliferation at Day 180 (CD8+ and CD4+ cells), and peak baseline fold change in microagglutination titer. T-cell proliferation data was not included as part of the models as proliferation data for 11 subjects was missing (the data had not been collected).

Before fitting the CCA models, the gene expression variable set was processed as follows:

1. probe sets corresponding to the same gene (same gene name) were collapsed by retaining the probe set per gene that had the highest absolute mean fold change from baseline for the respective post vaccination-day.

2. collapsed probe sets with an absolute fold change ≥ 1.5 were retained and used as gene variable set for the correlation analysis.

The 5 IMO variables were encoded as follows:

- CD4H: subject-specific peak fold change in %CD3+ CD4+ CD38+ HLA-DR+ T-cells (Days 14, 28, 56, 180).
- CD4B: subject-specific peak fold change in %CD3+ CD4+ BCL2+ KI67+ T-cells (Days 14, 28, 56, 180).
- CD8H: subject-specific peak fold change in %CD3+ CD8+ CD38+ HLA-DR+ T-cells (Days 14, 28, 56, 180).
- CD8B: subject-specific peak fold change in %CD3+ CD8+ BCL2+ KI67+ T-cells (Days 14, 28, 56, 180).
- MAGL: subject-specific peak fold change in Tularemia-specific microagglutination titer (Days 14, 28, 56, 180).

Prior to CCA, immunogenicity variables were transformed using the Box-Cox transformation to make their distributions more symmetric and unimodal (while normality is not required, it optimizes the distributional information used as part of the modeling process). To avoid over fitting ($n \ll g$ and collinearity among genes) a regularization step was applied. Optimal regularization parameters were estimated using leave-one-out cross validation. Significant canonical variate pairs were identified by manually inspecting scree plots. Individual variables were correlated against their significant canonical variates to obtain canonical loadings. Canonical loadings were squared to obtain the proportion of explained variance. Canonical loadings for each variable set were plotted and variables with low explained variance were filtered out (correlation < 0.5 or explained variance $< 25\%$).

2.10 Comparisons with viral vaccine microarray studies

RMA-normalized expression data obtained from yellow fever (YF-17D) vaccinees (Day 0, 3, 7) as well as trivalent influenza vaccine (TIV) (Day 0, 3, 7), and live attenuated influenza vaccine (LAIV) (Day 0, 3, 7) vaccinees were provided by Emory University. For each vaccine study, probe sets with a coefficient of variation (CV) higher than the lower quartile of all CVs were retained. Due to different Affymetrix array types and non-matching probe information (HG-U133 PM for 10-0019 Tularemia vaccine data and HG133 Plus 2 for YF-17D, TIV, and LAIV microarray data), the mean \log_2 fold change across gene sets with the same gene symbol (based on Affymetrix release 34 probe set annotations) was used for the comparative analysis. For each vaccine study and post-vaccination day, a paired-t test was applied to identify genes that were differentially expressed from baseline. A Welch t-test was used to identify differential fold changes between vaccine studies (Day 2 responses following DVC-LVS/USAMRIID-LVS vaccination were compared to Day 3 responses following YF-17D, TIV, or LAIV vaccination). The same fold change and FDR cut offs as described in **Section 2.5** were used. For gene set enrichment analysis, gene symbols were mapped to Ensembl gene IDs using Affymetrix HG-U133 PM and Hugo (accessed 05/12/2015) mappings. Only gene symbols represented in the 10-0019 Tularemia expression data set were analyzed using GSEA. For Ensembl gene IDs that mapped to multiple gene symbols, the

largest absolute t statistic was used. Genes were then ranked based on absolute t statistic and GSEA analysis was carried out as described in **Section 2.7**. The DVC/USAMRIID-LVS data was pooled when identifying enriched gene sets as well as DE genes. Tularemia vaccine group membership was retained and displayed in subject-level heatmaps when comparing differential gene lists.

2.11 Cell mediated immunity analysis

MFI values less than 0 after normalization of background fluorescence were set to 0. MFI values of 0 were imputed to 1 for fold calculations only. Similarly, percent cell activation values of 0 were imputed to 0.01 for fold change calculations only. Cytokines with concentrations less than the experimental lower limit of quantification (LLOQ) were imputed to 1/2 LLOQ. A 95% CI for the median measurement as well as median fold change from baseline for each time point and treatment group was obtained for each assay and marker combination using the bootstrap method with 1,000 bootstrap replicates each.

Table 84: Differentially expressed genes (vaccine study comparisons, LAIV (Influenza), Day 7 vs. 0). The average \log_2 fold change was used to combine probe sets with the same gene symbol prior to the analysis. Results are sorted by descending t-statistic. Gene annotations were obtained from Affymetrix (HT HG-U133 Plus PM Annotations, Release 34,10/24/13).

Gene Name	Gene Description	\log_2 FC	t-Statistic	P	FDR

KLHDC7B	kelch domain containing 7B	-0.64	-6.82	<0.0001	<0.0001
OAS2	2'-5'-oligoadenylate synthetase 2, 69/71kDa	-1.21	-7.00	<0.0001	<0.0001
XAF1	XIAP associated factor 1	-1.47	-7.20	<0.0001	<0.0001
OAS3	2'-5'-oligoadenylate synthetase 3, 100kDa	-1.54	-7.49	<0.0001	<0.0001
IRF7	interferon regulatory factor 7	-1.40	-7.52	<0.0001	<0.0001
ISG15	ISG15 ubiquitin-like modifier	-1.91	-7.73	<0.0001	<0.0001
SPATS2L	spermatogenesis associated, serine-rich 2-like	-0.79	-7.76	<0.0001	<0.0001
CMPK2	cytidine monophosphate (UMP-CMP) kinase 2, mitochondrial	-2.08	-7.78	<0.0001	<0.0001
RSAD2	radical S-adenosyl methionine domain containing 2	-2.48	-7.79	<0.0001	<0.0001
LDLR	low density lipoprotein receptor	-0.87	-7.94	<0.0001	<0.0001
IFI27	interferon, alpha-inducible protein 27	-3.19	-8.02	<0.0001	<0.0001
LINC00487	long intergenic non-protein coding RNA 487	-1.68	-8.03	<0.0001	<0.0001
IFI6	interferon, alpha-inducible protein 6	-1.78	-8.13	<0.0001	<0.0001
EPSTI1	epithelial stromal interaction 1 (breast)	-1.79	-8.25	<0.0001	<0.0001
OASL	2'-5'-oligoadenylate synthetase-like	-1.69	-8.28	<0.0001	<0.0001
IFI44	interferon-induced protein 44	-2.19	-8.66	<0.0001	<0.0001
EIF2AK2	eukaryotic translation initiation factor 2-alpha kinase 2	-1.09	-8.81	<0.0001	<0.0001
MX1	myxovirus (influenza virus) resistance 1, interferon-inducible protein p78 (mouse)	-1.98	-8.97	<0.0001	<0.0001
SIGLEC1	sialic acid binding Ig-like lectin 1, sialoadhesin	-2.46	-9.20	<0.0001	<0.0001
RGL1	ral guanine nucleotide dissociation stimulator-like 1	-1.48	-9.59	<0.0001	<0.0001
LAMP3	lysosomal-associated membrane protein 3	-2.12	-9.63	<0.0001	<0.0001
IFI44L	interferon-induced protein 44-like	-3.30	-9.72	<0.0001	<0.0001

Gene Name	Gene Description	\log_2 FC	t-Statistic	P	FDR
USP18	ubiquitin specific peptidase 18	-2.24	-10.20	<0.0001	<0.0001
HERC6	HECT and RLD domain containing E3 ubiquitin protein ligase family member 6	-1.20	-11.43	<0.0001	<0.0001

Table 86: Differentially expressed genes (vaccine study comparisons, DVC-LVS/USAMRIID-LVS (Tularemia) Day 7 vs. YF-17D (Yellow Fever) Day 7). The average \log_2 fold change was used to combine probe sets with the same gene symbol prior to the analysis. Results are sorted by descending t-statistic. Gene annotations were obtained from Affymetrix (HT HG-U133 Plus PM Annotations, Release 34,10/24/13).

Gene Name	Gene Description	\log_2 FC	t-Statistic	P	FDR
METTL3	methyltransferase like 3	0.59	4.28	<0.0001	0.0308
ERV3-2	endogenous retrovirus group 3, member 2	0.67	4.25	0.0001	0.0414

Day 14	Combined Study Groups	39	291	5	0.27	0.89	0.87	0.08	0.71

Table 93: Canonical correlation analysis summary statistics

Figures

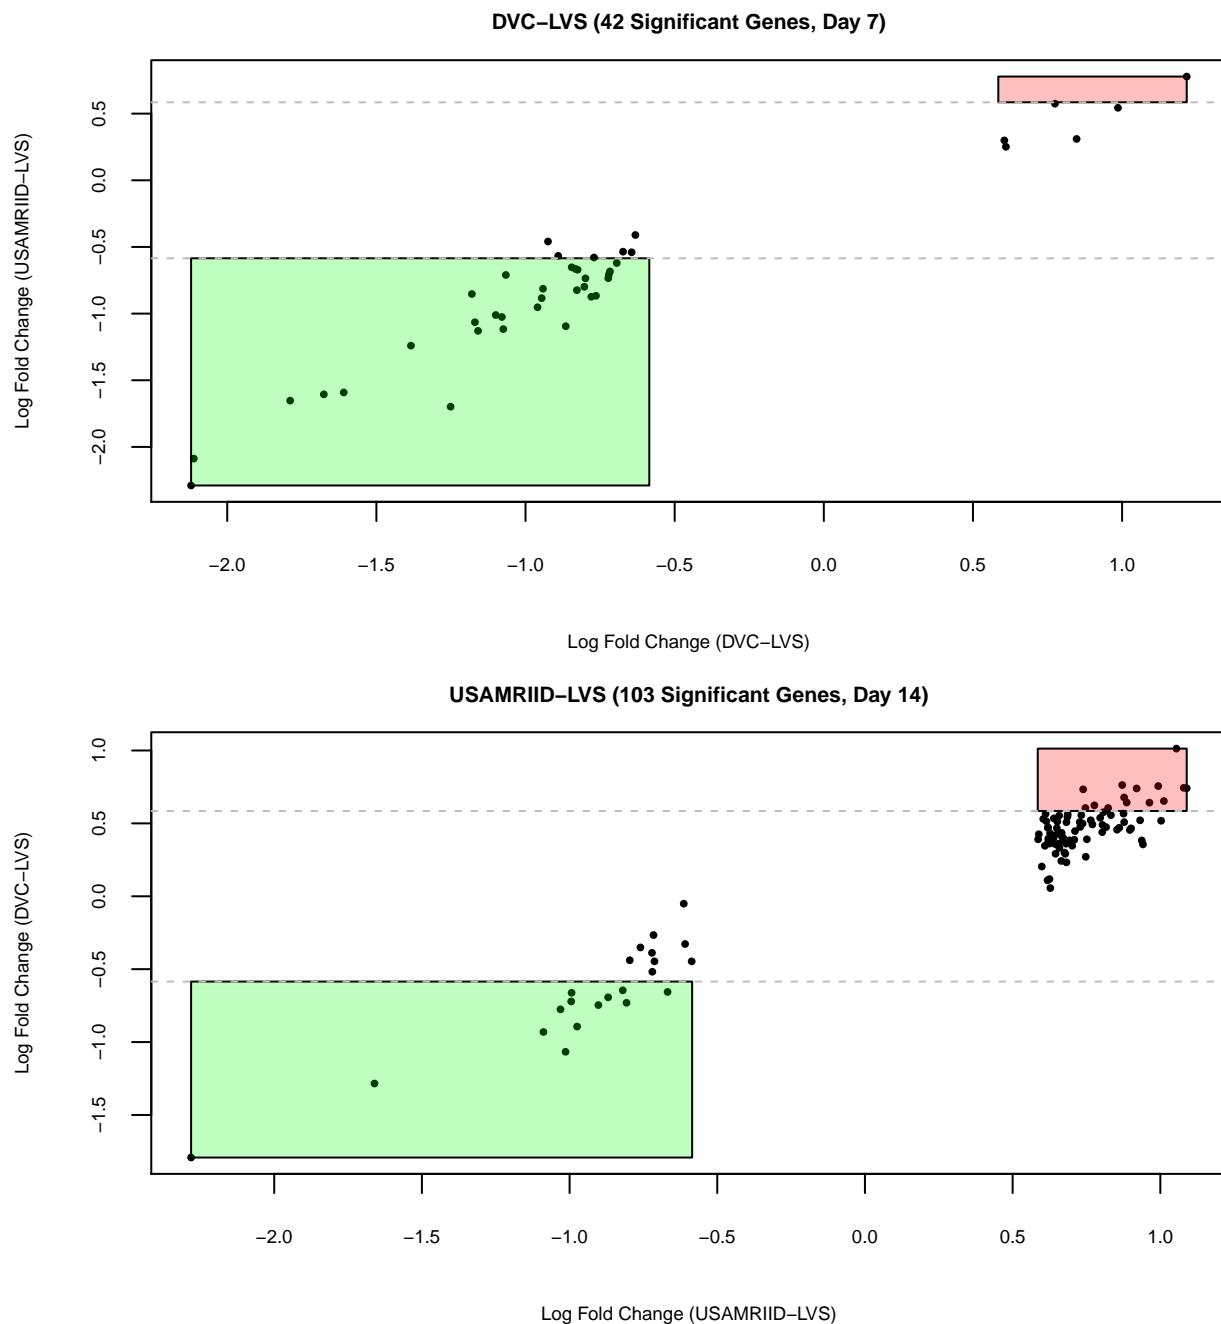

Figure 1: Scatter plot of fold changes of significant genes (DVC-LVS vs. USAMRIID-LVS, Day 7, 14). Fold change region in which both study groups exceed the upper fold change cut off is shaded in red. Fold change region in which both study groups are below the lower fold change cut off is shaded in green

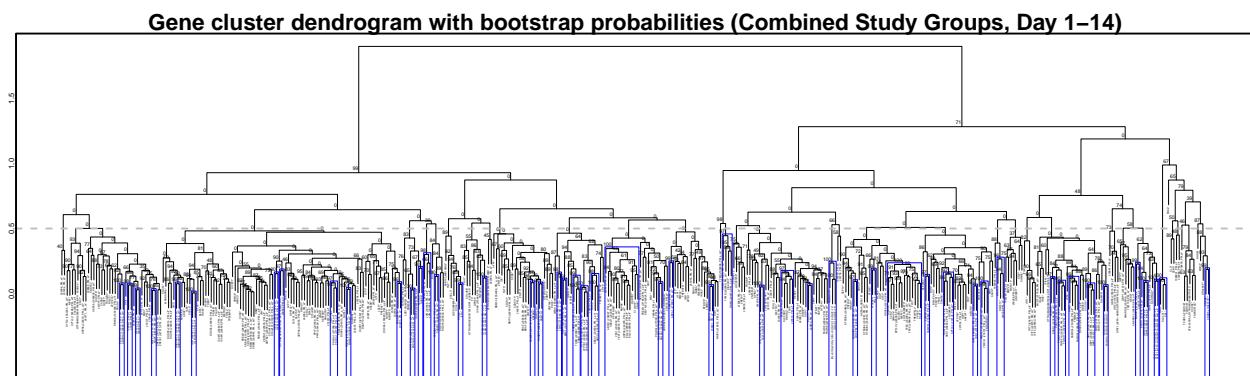

Figure 2: Gene cluster dendrogram with bootstrap probabilities (Combined Study Groups, Day 1–14). The y axis shows the distance at which clusters were formed by the complete linkage clustering algorithm based on uncentered Pearson correlation distance between log fold changes. Multiscale bootstrap probabilities are shown at each branch intersection. Significant clusters are highlighted in blue.

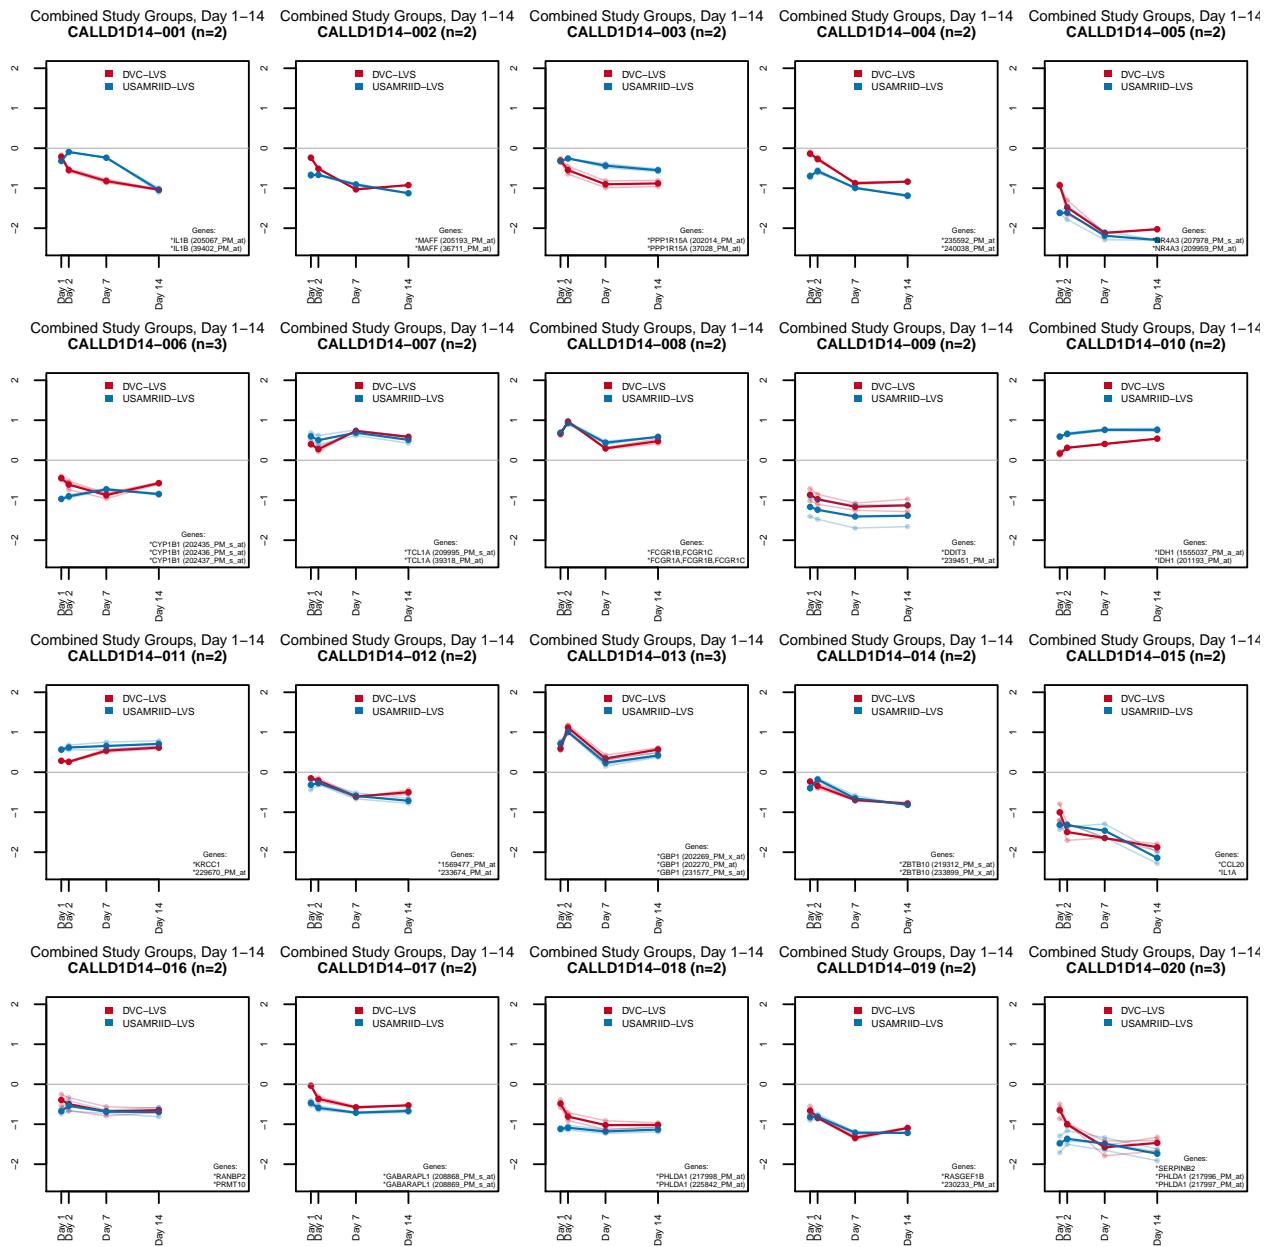

Figure 3: Gene cluster time trends of baseline \log_2 fold change by study group (Combined Study Groups, Day 1-14). Header indicates cluster ID. Mean \log_2 fold change across cluster genes is drawn in bold. Individual mean gene \log_2 fold changes are plotted in lighter colors.

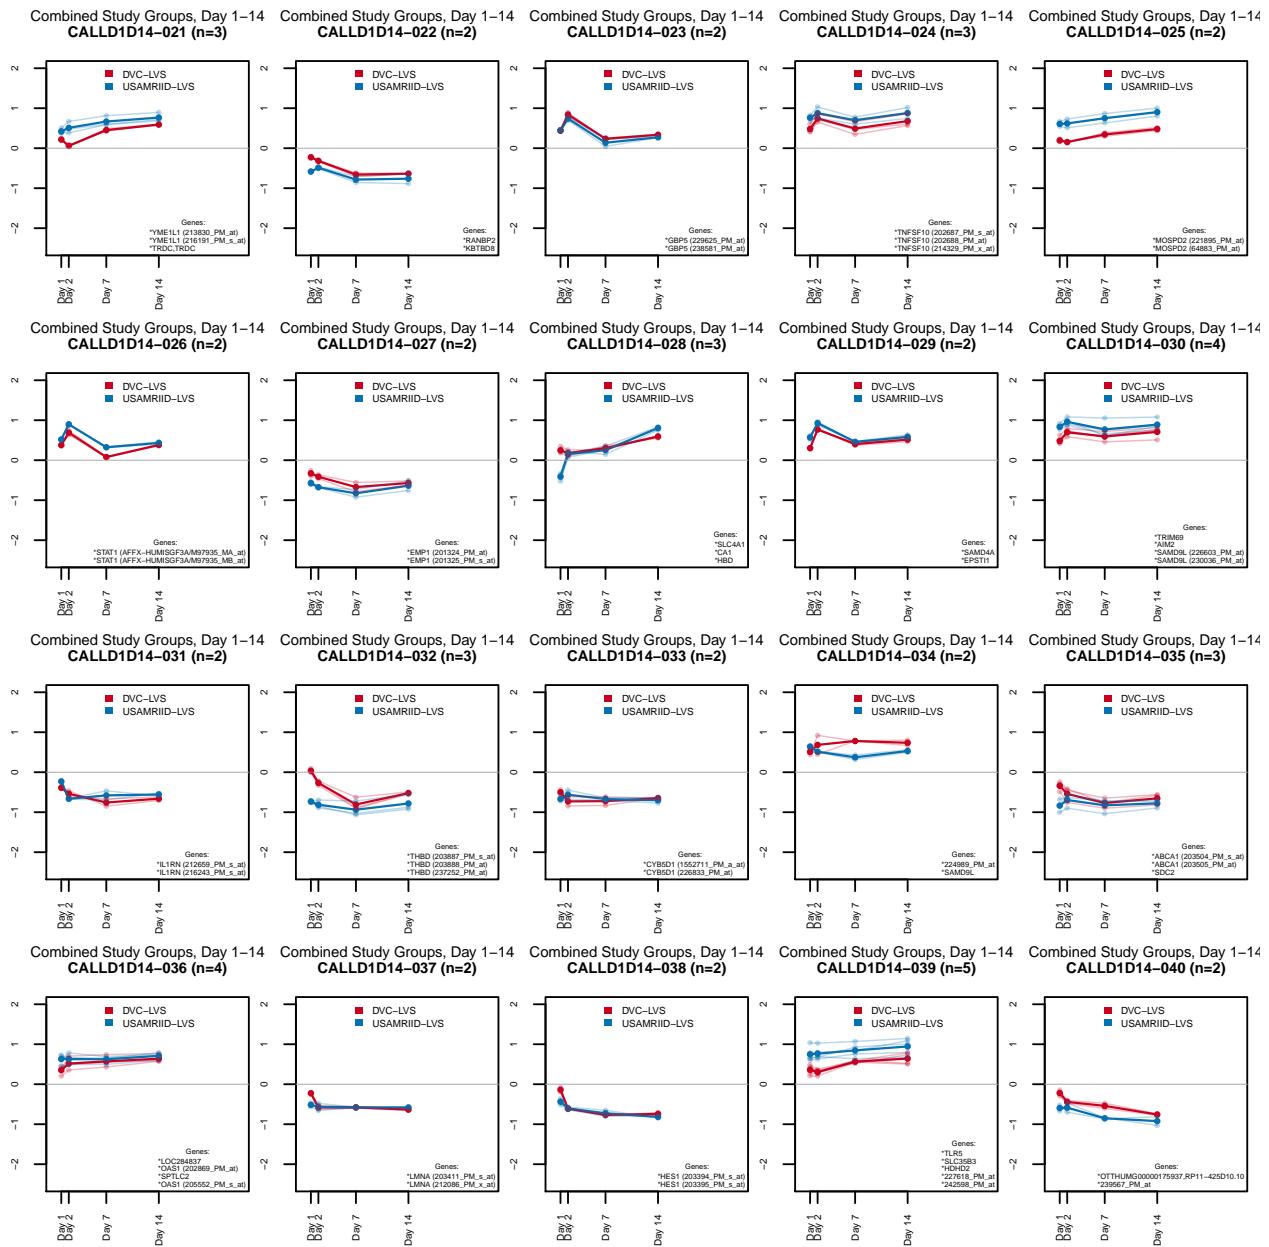

Figure 4: Gene cluster time trends of baseline \log_2 fold change by study group (Combined Study Groups, Day 1-14). Header indicates cluster ID. Mean \log_2 fold change across cluster genes is drawn in bold. Individual mean gene \log_2 fold changes are plotted in lighter colors.

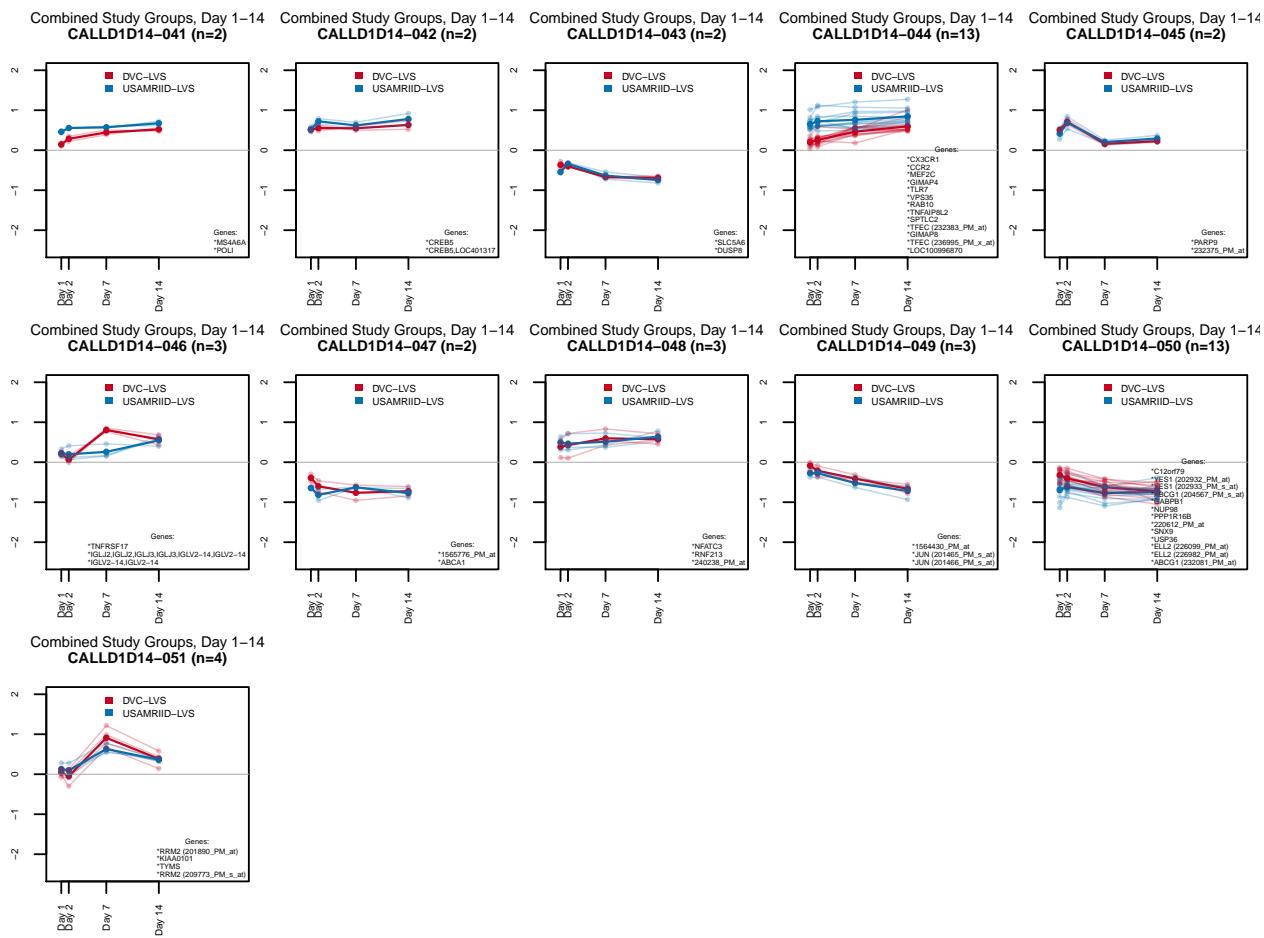

Figure 5: Gene cluster time trends of baseline \log_2 fold change by study group (Combined Study Groups, Day 1-14). Header indicates cluster ID. Mean \log_2 fold change across cluster genes is drawn in bold. Individual mean gene \log_2 fold changes are plotted in lighter colors.

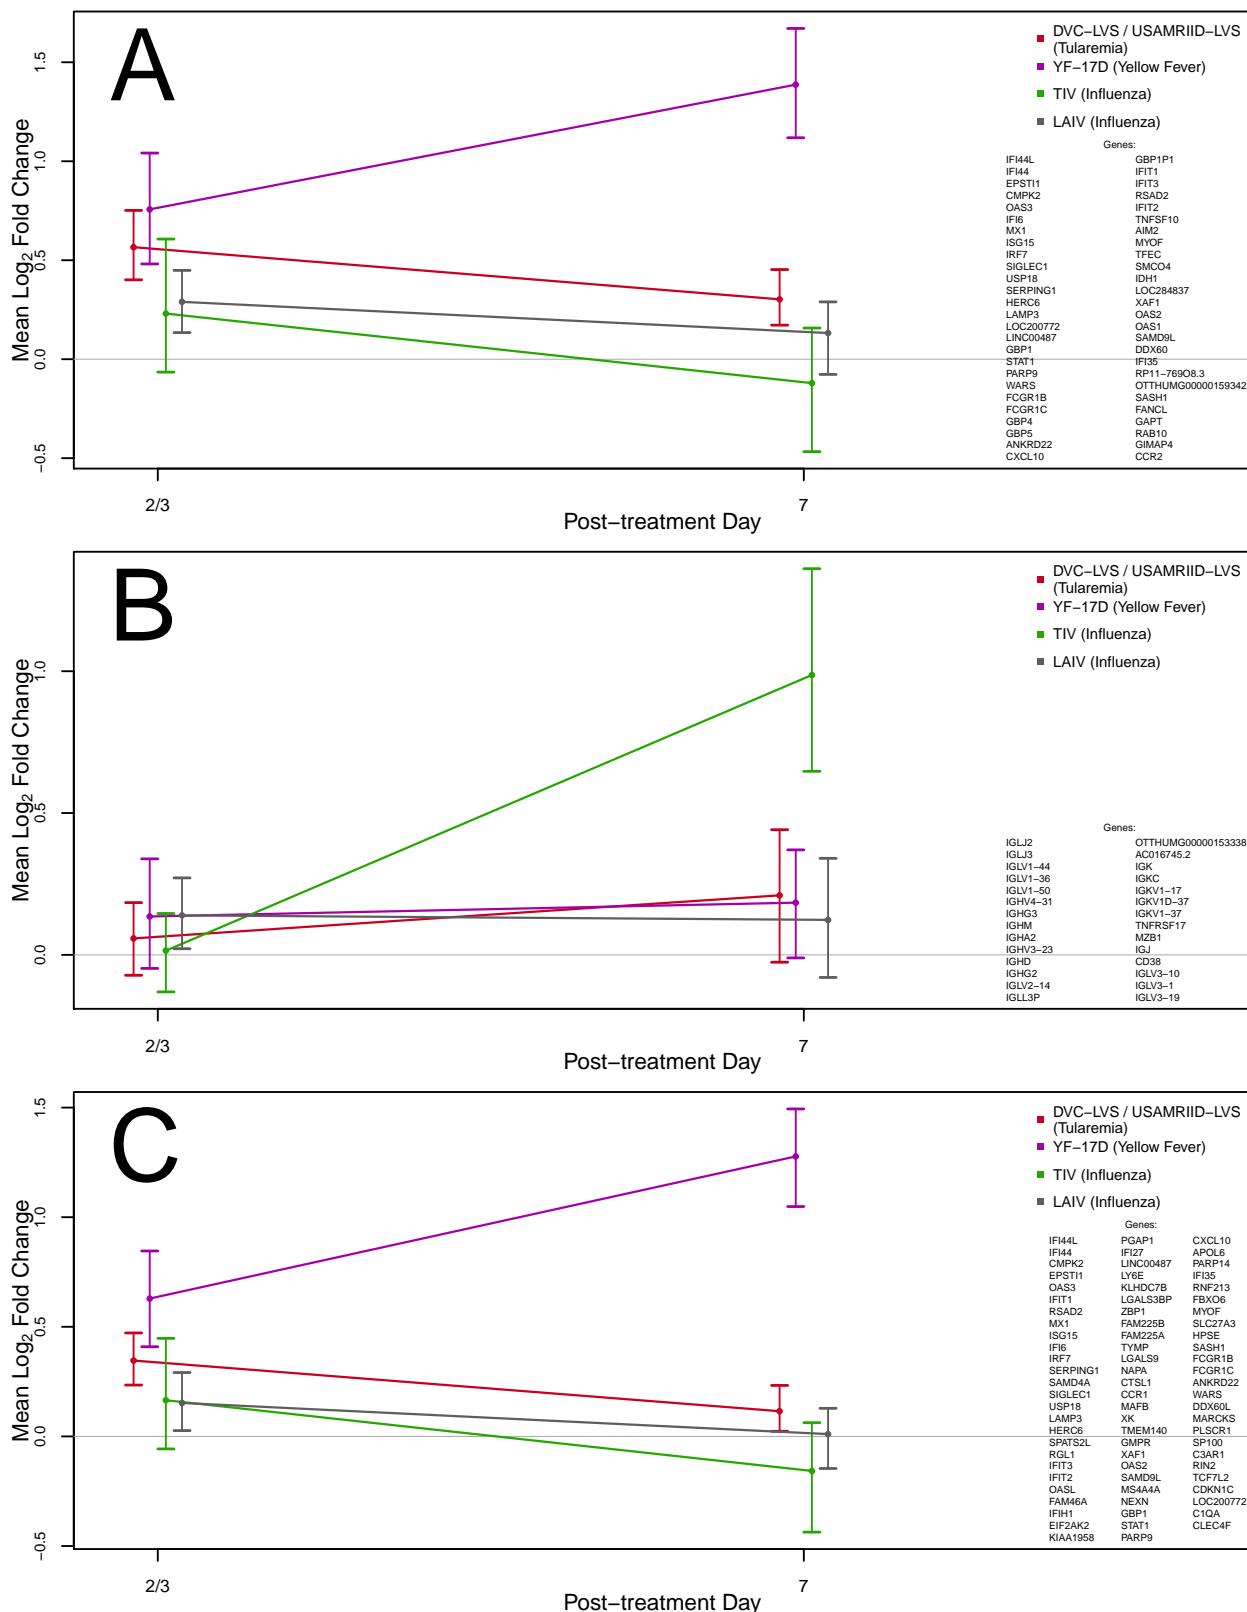

Figure 6: Time trends of mean \log_2 fold change and associated 95% bootstrap confidence intervals for gene clusters identified in subject-level heatmaps.

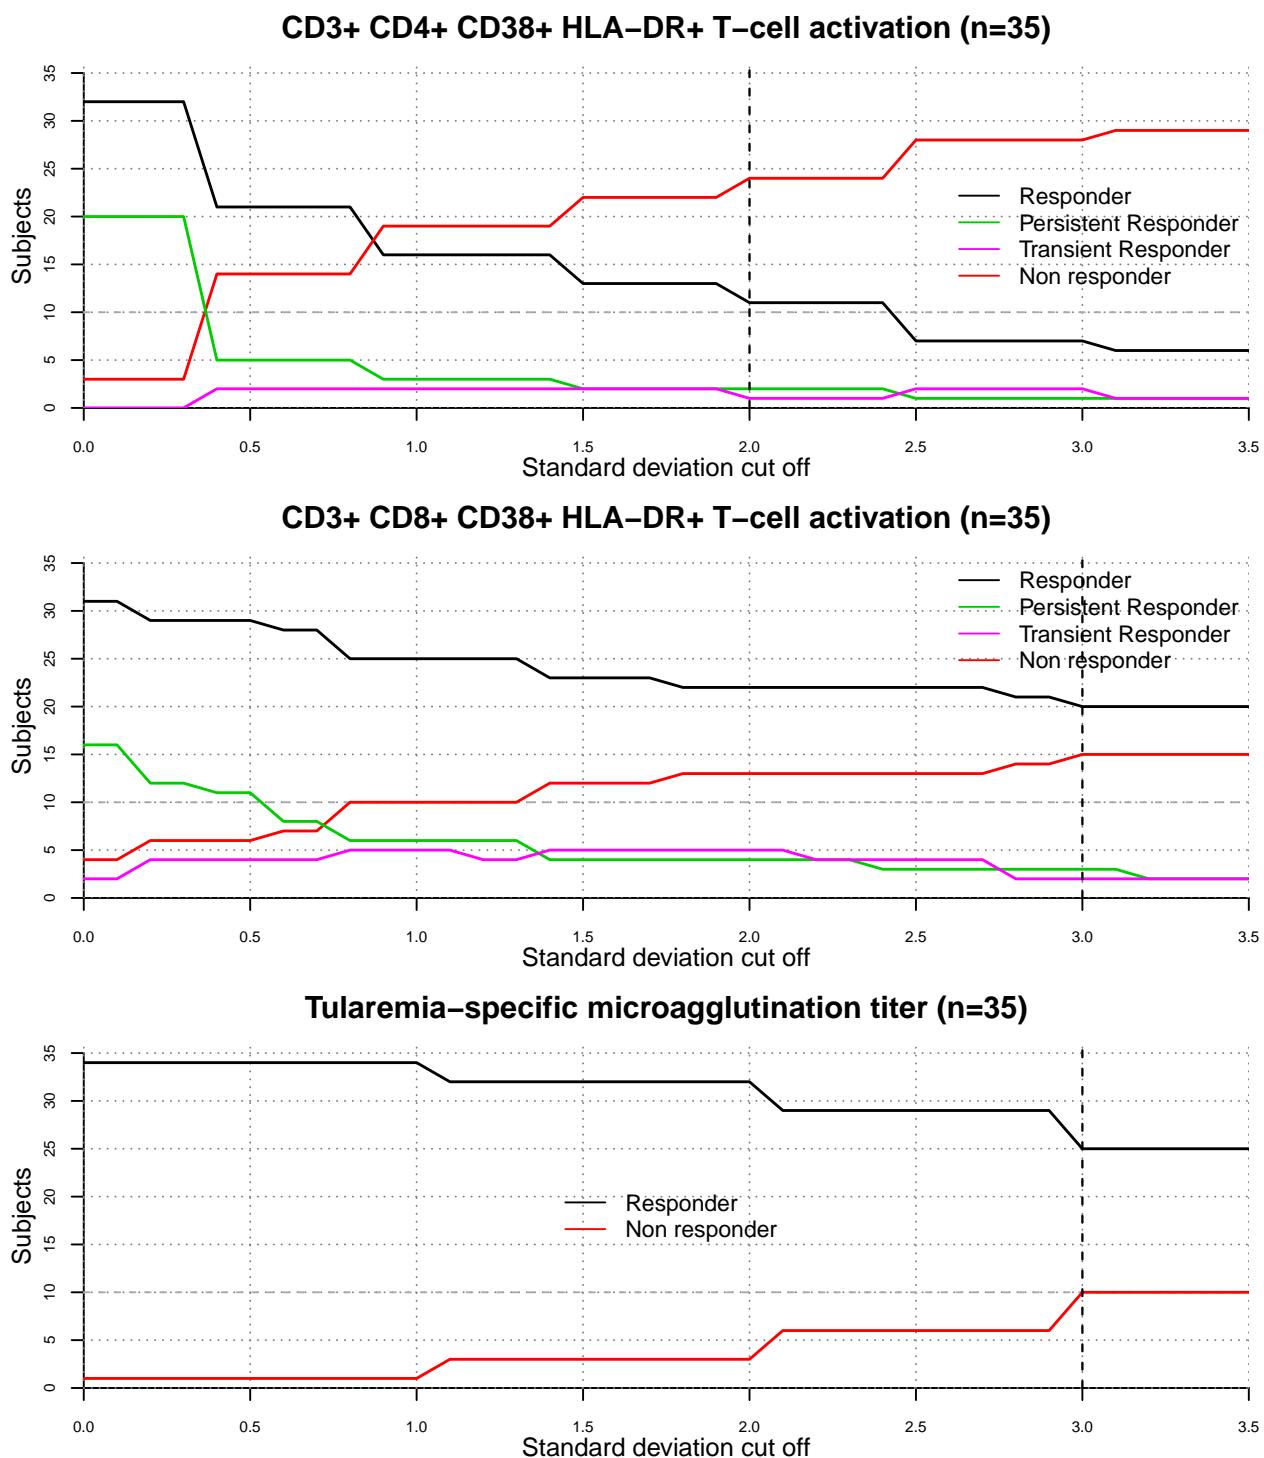

Figure 7: Number of subjects with microarray data for all post-vaccination days that pass a certain immune response cut off by assay. Y-axis: number of subjects, x-axis: the number of standard deviations above the baseline mean used to define responders (see Section 2.8 for details). The dashed black vertical line indicates the standard deviation cut off that was used for the analysis.

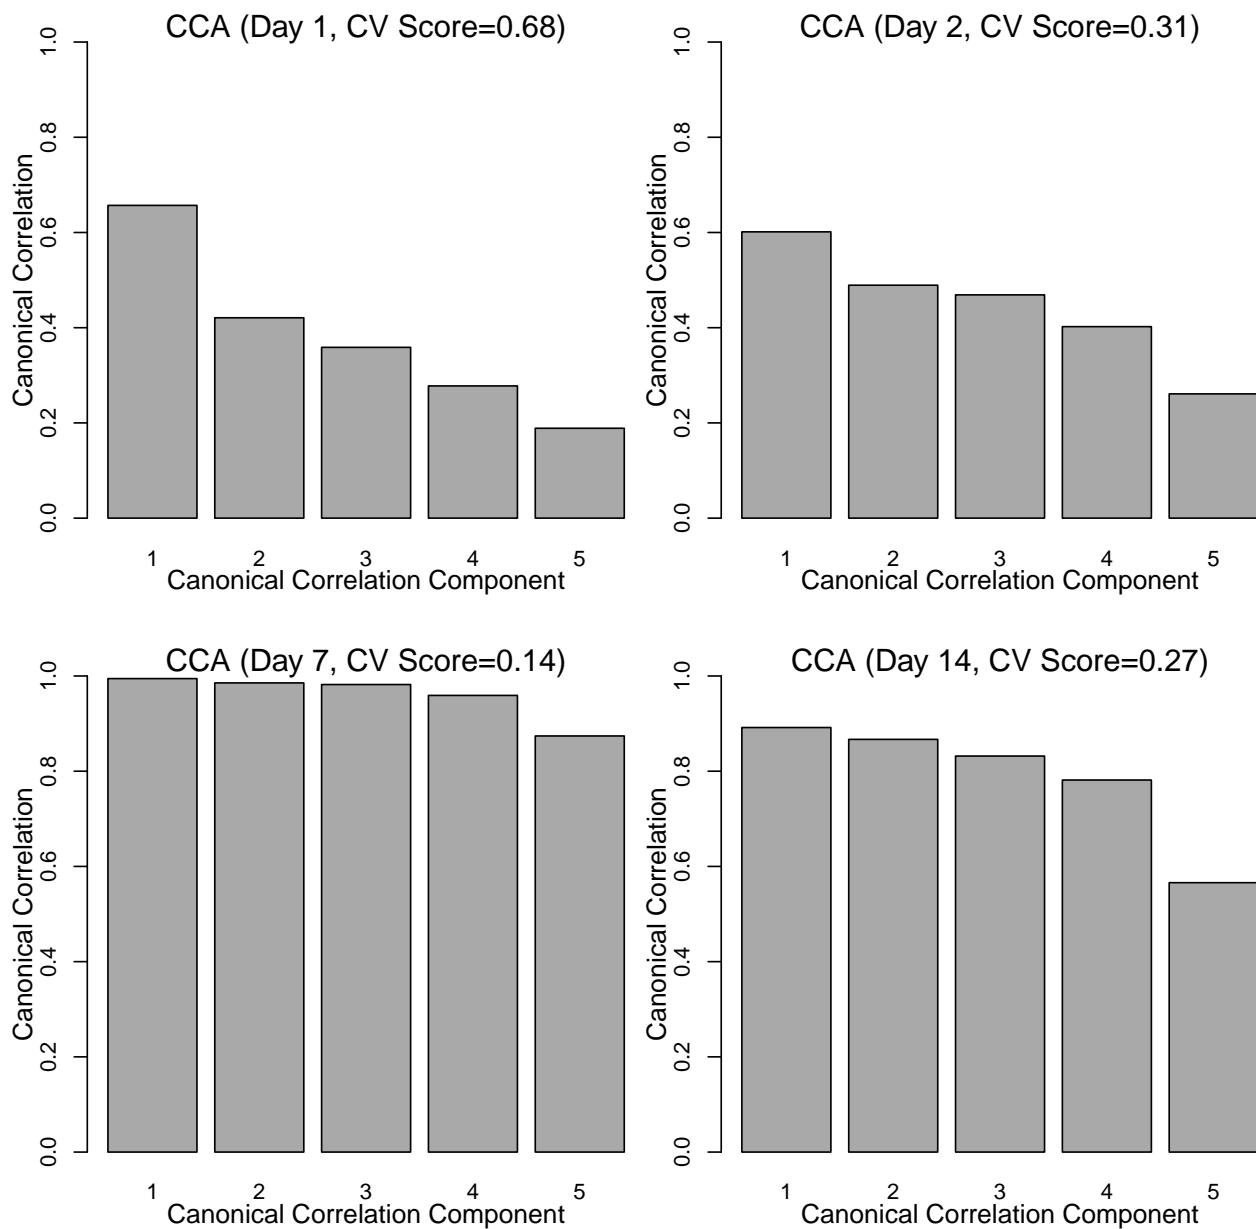

Figure 8: Canonical correlation scree plots for combined study groups. CV-score represents cross validation score.
