Abstract: Antibiotics have been the cornerstone of modern medicine saving lives by virtue of being able to cure infectious diseases and to prevent infections in those who are immune compromised. Their intense use has led to a surging increase in the incidence of antibiotic-resistant bacteria resulting in a desperate need for antibiotics with new mechanisms of action. As part of our search for new antimicrobials we have screened an in-house library of compounds and identified two 3-substituted-1*H*-imidazol-5-yl-1*H*-indoles as weak growth inhibitors (MIC 16 $\mu\text{g}/\text{mL}$) against methicillin-resistant *Staphylococcus aureus* (MRSA). An extensive library of analogues was prepared using the Van Leusen three-component reaction, biological evaluation of which led to the identification of two analogues (**26** and **32**) with favorable anti-MRSA activity ($\text{MIC} \leq 0.25 \mu\text{g}/\text{mL}$) which also lacked cytotoxic or hemolytic properties. The screening campaign also identified two derivatives, a phenethyl-indole-imidazole **57** and a 5-phenyl-1*H*-imidazole **111** that were non-toxic selective antifungals towards *Cryptococcus neoformans*. These results have identified 3-substituted-1*H*-imidazol-5-yl-1*H*-indoles and 5-phenyl-1*H*-imidazoles as new structural scaffolds for further investigation as anti-MRSA and anti-*C. neoformans* agents, respectively.

1. Introduction

New Zealand has a growing problem with *Staphylococcus aureus* infection, experiencing higher levels of incidence than other developed countries, with incidences of *S. aureus*-related hospitalizations highest in the under-five and over 75 year age groups [1–7]. Over the ten-year period of 2001–2011, the incidence of methicillin-susceptible *S. aureus* infections increased to 361 per 100,000, with MRSA infection (covering non-multidrug resistant MRSA and multidrug resistant MRSA) accounting for an additional 12% of cases. In the case of children under the age of 15, annual average hospitalization rates for *S. aureus* skin and soft tissue infection (SSTI) increased to 522 per 100,000 population (2011), with sub-population analysis identifying Māori and Pacific children with rates of 1488 and 1215 per 100,000 population, respectively [1–7].

Front-line treatments for SSTI in New Zealand are the topical antimicrobials fusidic acid and mupirocin. During the 1993–2012 timeframe, community prescribing rates for fusidic acid increased dramatically (likely due to the drug becoming a Government-subsidized treatment option) and this was matched with a corresponding increase in fusidic acid-resistant MRSA [8,9]. Unfortunately, the widespread, and largely unregulated,

use of this valuable topical antimicrobial resource will ultimately lead to the need for more treatment options.

We have recently screened an in-house library of natural products and synthetic compounds against a panel of bacterial and fungal pathogens [10,11] which led to the discovery of a compound class (Figure 1) that exhibited activity exclusively against methicillin-resistant *Staphylococcus aureus* (MRSA). Of the compounds screened, 3-substituted-1*H*-imidazol-5-yl-1*H*-indole (“indole-imidazole”) compounds **1** and **2** were found to weakly inhibit the growth of MRSA with MIC of 16 µg/mL (Table 1) while a closely related 5-fluoro analogue **3** (Supplementary Figures S1–S3) was devoid of activity.

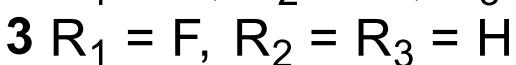

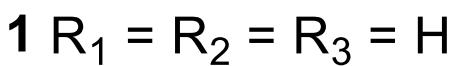

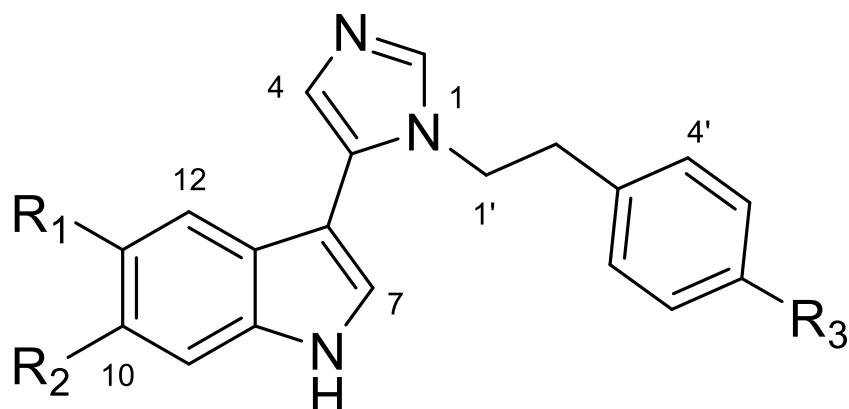

Figure 1. Structures of indole-imidazole compounds **1–3**.

Similarly functionalized 1*H*-imidazol-5-yl-1*H*-indoles have been recently reported as active towards crop-related fungi [12] and as 5-HT₇ serotonin receptor agonists [13]. Variants with increased substitution such as the marine natural products topsentins [14,15] and nortopsentins [16,17] have been shown to exhibit cytotoxic, antiviral and antifungal activities while analogues of the natural product meridianin exhibit antibiotic adjuvant properties [18]. Additionally, 1-benzenesulfonyl-1*H*-indoles have been reported as 5-HT₆ receptor agonists [19]. With this relatively limited literature on 3-substituted 1*H*-imidazol-5-yl-1*H*-indoles, we undertook a study to further explore the antimicrobial properties of this class of molecule by preparing a more diverse array of analogues that explored the influence of the imidazole *N*-substituent and indole halogen substitution on biological activity. Herein we report on the synthesis and biological evaluation of a diverse set of analogues of hit compounds **1** and **2**.

2. Results and Discussion

A set of 39 new analogues were prepared (**4–42**) (Figure 2 and Supplementary Materials Figures S4–S42) utilizing the Van Leusen three-component reaction [20]. This two-step, one-pot reaction starts with *in situ* generation of an imine by condensation of an indole-3-carbaldehyde with an amine, followed by reaction with *p*-toluenesulfonylmethyl isocyanide (TosMIC) and K₂CO₃ at 60 °C for 24 h (Schemes 1 and 2).

Scheme 2. Proposed reaction mechanism of Van Leusen three-component reaction.

The set of analogues included the indole fragment bearing 5- and 6- halogen substituents of bromine, chlorine, and fluorine, as well as an unsubstituted indole. The differently substituted indoles offer an opportunity to probe the effect of the electronics of the indole ring against antimicrobial activity. Six amines were used to introduce variation at the R₃ position (Figure 2). These included oxygenated amines such as *p*-methoxybenzylamine, *p*-methoxyphenethylamine, 2,5-dimethoxyphenethylamine and homopiperonylamine probe for hydrogen bond interactions. The phenethylamines explore an increased alkyl chain length between the aromatic group of the amine and the imidazole linker while *p*-iodobenzylamine can be used to directly compare with *p*-methoxybenzylamine the difference in bioactivity in the presence of a bulky halogen.

The antimicrobial activities of compounds **4–42** were determined against a panel of bacterial (*Staphylococcus aureus*, methicillin-resistant *S. aureus*, *Pseudomonas aeruginosa*, *Escherichia coli*, *Klebsiella pneumoniae* and *Acinetobacter baumannii*) and two fungal (*Candida albicans* and *Cryptococcus neoformans*) pathogens. The results are summarized in Table 1. Antimicrobial selectivity was observed towards the Gram-positive bacteria *S. aureus* and *S. aureus* MRSA, with MIC values ranging from ≤ 0.25 $\mu\text{g}/\text{mL}$ to >200 $\mu\text{g}/\text{mL}$. None of the compounds exhibited activity against the Gram-negative bacteria *P. aeruginosa*, *E. coli*, *A. baumannii* or *K. pneumoniae* or the fungus *C. albicans* at a single dose of 32 $\mu\text{g}/\text{mL}$. Of the compound set, only **9** exhibited (weak, MIC 16 $\mu\text{g}/\text{mL}$) activity towards the fungus *C. neoformans*.

The more active anti-MRSA compounds were found to contain halogen substitution on the indole, with the 5- position analogues typically being more active than their 6-substituted counterparts, and the presence of an *N*-phenethyl substituent on the imidazole ring, e.g., **26** (MIC ≤ 0.25 $\mu\text{g}/\text{mL}$), **27** (8 $\mu\text{g}/\text{mL}$) and **32** (4 $\mu\text{g}/\text{mL}$). The set of compounds were also evaluated for cytotoxicity against a human embryonic kidney cell line (HEK293) and for hemolytic activity towards human red blood cells (Table 1). Of the compounds tested, none exhibited hemolytic activity at a single dose of 32 $\mu\text{g}/\text{mL}$ but quite a few were identified as exhibiting some degree of cytotoxicity. Of note however was the lack of cytotoxicity observed for the two more active anti-MRSA compounds **26** and **32**.

A further, more-expansive set of analogues was prepared (Figures 3 and 4) that explored the influence of 4- and 7-halogen or 5/6-methoxy substituted indoles bearing benzyl, 2-phenethyl or 3-phenylpropyl (compounds 43–72) or indolemethylene or indole-ethyl (73–88) and *n*-pentyl (89–96) side chains. In addition, analogues 97–102 were prepared that retained a common 5-chloroindole fragment, identified as being associated with activity in set 1, but with a wider variation in R₃ fragment (Figure 3), while analogues 103–116 explored replacement of the indole fragment with a phenyl or *p*-methoxyphenyl group (Figure 4). A total of 74 compounds (43–116) were prepared in this library (Figures S43–S116).

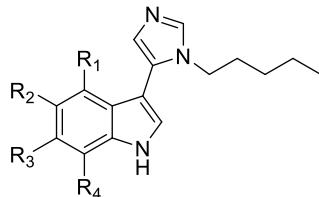

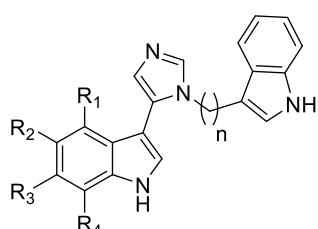

Analogues 43–116 were evaluated for biological activity in the same manner as the earlier compound sets. Surprisingly, from the 74 analogues tested, none were considered active towards MRSA (MIC 32 $\mu\text{g/mL}$ or greater). This result suggests that the structural requirements for activity of the indole-imidazole scaffold towards MRSA is very precise/narrow, with halogenation on 5-position of the indole and a methoxy phenethyl sidechain, making it difficult to identify ways forward in further optimizing the structure. Of note from this set of compounds was the observation of potent antifungal activity against *C. neoformans* (MIC values of ≤ 0.25 $\mu\text{g/mL}$) for both 6-methoxy-phenethyl-indole-imidazole 57 and 5-phenyl-1*H*-imidazole 111 (Table 1): the lack of cytotoxicity and hemolytic activity for these two compounds identifies them as selective hits and worthy of further investigation.

Currently, the mechanism of antimicrobial action of this compound class is unknown. Thus, we sought to investigate the mechanism of action of this compound class against *S. aureus* using compound 6, which exhibited strong activity against *S. aureus*. In a preliminary investigation, compound 6 exhibited only very weak membrane depolarization of *S. aureus*, suggesting the cellular target in bacteria is not membrane-related. Further investigation to improve the antimicrobial and antifungal activity and identify the mechanism of action of these compounds is underway.

3. Materials and Methods

3.1. General Experimental Procedures

High-resolution mass spectra were recorded using a MicrOTOF-QII mass spectrometer (Bruker Daltonics, Bremen, Germany). Melting points were determined on a Reichert-Hofler block and are uncorrected. Infra-red spectra were recorded on a Perkin Elmer Spectrum 100 Fourier Transform infrared spectrometer equipped with a universal ATR accessory. NMR spectra were recorded using a Bruker Avance 400 MHz or Avance III-HD 500 spectrometer operating at 400 or 500 MHz for ^1H nuclei and 100 or 125 MHz for ^{13}C nuclei. Proto-deutero solvents signals were used as internal references ($\text{DMSO}-d_6$: δ_{H} 2.50, δ_{C} 39.52; CDCl_3 : δ_{H} 7.26, δ_{C} 77.16). For ^1H NMR, the data are quoted as position (δ), relative integral, multiplicity (s = singlet, d = doublet, t = triplet, m = multiplet, dd = doublet of doublets, ddd = doublet of doublet of doublets, tt = triplet of triplets, br = broad), coupling constant (J , Hz), and assignment to the atom. The ^{13}C NMR data are quoted as position (δ), and assignment to the atom. Standard Bruker pulse sequences were utilized. Pressurized (flash) column chromatography was carried out with Kieselgel 60 0.063–0.200 mesh (Merck, Darmstadt, Germany). Analytical thin layer chromatography (TLC) was carried out on 0.2 mm thick plates of Kieselgel F₂₅₄ or DC-Kieselgel 60 RP-18 F_{254S} (Merck). All samples were determined to >95% purity.

3.2. Synthesis

3.2.1. General Procedure

A solution of aldehyde (1 eq.) and amine (1 eq.) in DMF (1 mL) was stirred for 3 h under N_2 atmosphere. To the stirred solution was added solid K_2CO_3 (1 eq.) and *p*-toluenesulfonylmethyl isocyanide (1 eq.) before heating to 60 °C for 18 h. The reaction mixture was cooled to room temperature and quenched with H_2O (30 mL). The aqueous layer was extracted with EtOAc (30 mL), and the organic layer was washed with H_2O (3 × 30 mL) then brine (3 × 30 mL), dried over anhydrous MgSO_4 and concentrated under reduced pressure.

3.3. Biological Evaluation

3.3.1. Antimicrobial Assays

The susceptibility of *S. aureus* (ATCC25923) to antibiotics and compounds was determined in microplates using the standard broth dilution method in accordance with the recommendations of the Comité de l’AntibioGramme de la Société Française de Microbiologie (CA-SFM) as previously described. Briefly, the minimal inhibitory concentrations (MICs) were determined with an inoculum of 10⁵ CFU in 200 μL of Mueller-Hinton broth (MHB) containing two-fold serial dilutions of each drug. The MIC was defined as the

lowest concentration of drug that completely inhibited visible growth after incubation for 18 h at 37 °C. To determine all MICs, the measurements were independently repeated in triplicate [21].

Additional antimicrobial evaluation against *Staphylococcus aureus* MRSA (ATCC43300), *Pseudomonas aeruginosa* (ATCC27853), *Escherichia coli* (ATCC25922), *Klebsiella pneumoniae* (ATCC700603), *Acinetobacter baumannii* (ATCC19606), *Candida albicans* (ATCC90028), and *Cryptococcus neoformans* (ATCC208821) was undertaken at the Community for Open Antimicrobial Drug Discovery at The University of Queensland (Australia) according to their standard protocols [22]. For antimicrobial assays, the tested strains were cultured in either Luria broth (LB) (In Vitro Technologies, USB75852, Noble Park North, Australia), nutrient broth (NB) (Becton Dickinson, 234000, Macquarie Park, Australia), or cation-adjusted MHB at 37 °C overnight. A sample of culture was then diluted 40-fold in fresh MHB and incubated at 37 °C for 1.5–2 h. The compounds were serially diluted 2-fold across the wells of 96-well plates (Corning 3641, Tewksbury, MA, USA, nonbinding surface), with compound concentrations ranging from 0.015 to 64 µg/mL, plated in duplicate. The resultant mid log phase cultures were diluted to the final concentration of 1×10^6 CFU/mL; then, 50 µL was added to each well of the compound containing plates giving a final compound concentration range of 0.008 to 32 µg/mL and a cell density of 5×10^5 CFU/mL. All plates were then covered and incubated at 37 °C for 18 h. Resazurin was added at 0.001% final concentration to each well and incubated for 2 h before MICs were read by eye.

For the antifungal assay, fungi strains were cultured for 3 days on yeast extract-peptone dextrose (YPD) agar at 30 °C. A yeast suspension of 1×10^6 to 5×10^6 CFU/mL was prepared from five colonies. These stock suspensions were diluted with yeast nitrogen base (YNB) (Becton Dickinson, 233520) broth to a final concentration of 2.5×10^3 CFU/mL. The compounds were serially diluted 2-fold across the wells of 96-well plates (Corning 3641, nonbinding surface), with compound concentrations ranging from 0.015 to 64 µg/mL and final volumes of 50 µL, plated in duplicate. Then, 50 µL of the fungi suspension that was previously prepared in YNB broth to the final concentration of 2.5×10^3 CFU/mL was added to each well of the compound-containing plates, giving a final compound concentration range of 0.008 to 32 µg/mL. Plates were covered and incubated at 35 °C for 36 h without shaking. *C. albicans* MICs were determined by measuring the absorbance at OD₅₃₀. For *C. neoformans*, resazurin was added at 0.006% final concentration to each well and incubated for a further 3 h before MICs were determined by measuring the absorbance at OD_{570–600}.

Colistin and vancomycin were used as positive bacterial inhibitor standards for Gram-negative and Gram-positive bacteria, respectively. Fluconazole was used as a positive fungal inhibitor standard for *C. albicans* and *C. neoformans*. The antibiotics were provided in 4 concentrations, with 2 above and 2 below its MIC value, and plated into the first 8 wells of column 23 of the 384-well NBS plates. The quality control (QC) of the assays was determined by the antimicrobial controls and the Z'-factor (using positive and negative controls). Each plate was deemed to fulfil the quality criteria (pass QC), if the Z'-factor was above 0.4, and the antimicrobial standards showed full range of activity, with full growth inhibition at their highest concentration, and no growth inhibition at their lowest concentration.

3.3.2. Cytotoxicity Assays

For the HEK293 cytotoxicity assay, cells were counted manually in a Neubauer hemocytometer and plated at a density of 5000 cells/well into each well of the 384-well plates containing the $25 \times$ (2 µL) concentrated compounds. The medium used was Dulbecco's modified eagle medium (DMEM) supplemented with 10% fetal bovine serum (FBS). Cells were incubated together with the compounds for 20 h at 37 °C, 5% CO₂. To measure cytotoxicity, 5 µL (equals 100 µM final) of resazurin was added to each well after incubation, and incubated for further 3 h at 37 °C with 5% CO₂. After final incubation fluorescence intensity was measured as Fex 560/10 nm, em 590/10 nm (F_{560/590}) using a Tecan M1000 Pro monochromator plate reader. CC₅₀ values (concentration at 50% cytotoxicity)

city) were calculated by normalizing the fluorescence readout, with 74 µg/mL tamoxifen as negative control (0%) and normal cell growth as positive control (100%). The concentration-dependent percentage cytotoxicity was fitted to a dose response function (using Pipeline Pilot) and CC₅₀ values determined [22].

3.3.3. Hemolytic Assay

Human whole blood was washed three times with 3 volumes of 0.9% NaCl and then resuspended in same to a concentration of 0.5×10^8 cells/mL, as determined by manual cell count in a Neubauer hemocytometer. The washed cells were then added to the 384-well compound-containing plates for a final volume of 50 µL. After a 10 min shake on a plate shaker the plates were then incubated for 1 h at 37 °C. After incubation, the plates were centrifuged at 1000 g for 10 min to pellet cells and debris, 25 µL of the supernatant was then transferred to a polystyrene 384-well assay plate. Hemolysis was determined by measuring the supernatant absorbance at 405 nm (OD₄₀₅). The absorbance was measured using a Tecan M1000 Pro monochromator plate reader. HC₁₀ and HC₅₀ (concentration at 10% and 50% hemolysis, respectively) were calculated by curve fitting the inhibition values vs. log(concentration) using a sigmoidal dose–response function with variable fitting values for top, bottom and slope [22].

3.3.4. Membrane Depolarization Assay

S. aureus (ATCC25923) was grown in MH II broth for 24 h at 37 °C. After reaching an OD_{600 nm} of 0.5, cells were centrifuged ($3600 \times g$ for 20 min at 20 °C) and washed twice with buffered sucrose solution (250 mM), magnesium sulfate solution (25 mM) and Hepes (5 mM) (pH = 7.2). The fluorescent dye 3,3'-diethylthiacarbocyanine iodide DiSC₃(5) was added to a final concentration of 5 µM and was incubated with the suspensions for 5 min at 37 °C to allow the dye incorporation into the polarized membranes. 10 µL of compound was then added to 90 µL of the fluorescent suspensions at different concentrations ranging from 200 µM to 25 µM. Fluorescence measurements were recorded for 20 minutes (excitation wavelength 622 nm, emission wavelength 690 nm).

The difference in the relative fluorescence values (RFU) from the control containing only buffer and the control containing bacteria treated only with cetyltrimethylammonium bromide (CTAB 1%) is taken as the maximum level of depolarization. Assays were performed in three independent experiments. Blank determined by using no compound. Maximum RFU determined by using CTAB 0.1%

Equation used:

$$\frac{(\text{RFU of the compound} - \text{RFU of the blank}) \times 100}{\text{RFU of the maximum}}$$

4. Conclusions

In a bid to combat the surging increase of antibiotic-resistant bacteria a screening programme of a library of natural products, semi-synthetics and synthetic compounds was initiated targeting the a subset of the ESKAPE pathogens. Following our discovery of weak anti-MRSA activity associated with two 3-substituted-1*H*-imidazol-5-yl-1*H*-indoles we have synthesized a further 99 analogues as well as 14 examples of structurally related 5-phenyl-1*H*-imidazoles. Surprisingly few examples from the extended set of analogues exhibited antimicrobial properties, with only two examples (**26** and **32**) identified as being promising non-toxic selective anti-MRSA compounds. Of note was the identification of two analogues, **57** (a phenethyl-indole-imidazole) and **111** (a 5-phenyl-1*H*-imidazole) as being non-toxic selective antifungals towards *C. neoformans*. Further elaboration of these anti-MRSA and antifungal compounds will be the subject of future research.
