Abstract: Wireless communication is essential for the infrastructure of a healthcare system. This bidirectional communication is used for data collection and to control message delivery. Wireless communication is applied in industries as well as in our daily lives, e.g., smart cities; however, highly reliable communication may be more difficult in environments with low power consumption, many interferences, or IoT wireless network issues due to resource limitations. In order to solve these problems, we investigated the existing three-party password-authenticated key exchange (3PAKE) and developed an enhanced protocol. Currently, Lu et al. presented a 3PAKE protocol to improve the security flaws found in Farash and Attari's protocol. This work revisits the protocol proposed by Lu et al. and demonstrates that, in addition to other security weaknesses, the protocol does not provide user anonymity which is an important issue for healthcare environment, and is not secure against insider attacks that may cause impersonation attacks. We propose a secure biometric-based efficient password-authenticated key exchange (SBAKE) protocol in order to remove the incidences of these threats, and present an analysis regarding the security and efficiency of the SBAKE protocol for practical deployment.

Keywords: authentication; security; key agreement; healthcare; wireless communication

## 1. Introduction

Healthcare systems have emerged as exchangers of information that utilize the internet to discern health issues. The implementation of this system has magnified privacy and security issues. Innovative technologies like artificial intelligence (AI) and internet of things (IoT) enable internet-connected "things" to analyze information via platforms for various services that are accessible to users. As various devices communicate using the existing network infrastructure, we must evaluate whether they are not compromised or connected with malicious adversaries, and permission must be obtained to access each device while establishing a connection. Moreover, protecting anonymity and privacy requires the employment of effective authentication and key management schemes. The password-authenticated key exchange (PAKE) protocol ensures that information transmitted among communication entities is available to the authorized party. The initial works, i.e., Bellovin-Merritt's two-party PAKE (2PAKE) [1] protocol proposals [2–5] are widely applied to establish session keys between two communicating parties in various communication environments. It is known that 2PAKE protocols strain storage capacity in large-scale peer-to-peer architectures. In order to effectively overcome this problem, researchers developed three-party password-authenticated key exchange (3PAKE) protocols [6–11], which enable two users to generate a shared cryptographically-strong key with the support of

an authentication server over an insecure open network. Potential security risks, privacy issues, and efficiency are still challenging tasks that must be achieved in order to enhance protection in IoT support 3PAKE. Many proposed PAKE protocols involve the use of a server's public key or a smart card [8,12–15], or both, to protect the user's password. Constructing a server's public key through key generation and key management constrains the capacity for greater complexity and increases the computational costs of the protocol, while using a smart card can weaken security due to the resultant exposure to side-channel attacks [16] that can disclose sensitive information stored on a smart card.

In [17], Huang proposed a simple 3PAKE protocol that does not involve a smart card. Following its publication, Yoon and Yoo figured out that Huang's protocol could not withstand an undetectable online password guessing attack [18]. Then, using the undetectable online password guessing attack, Tallapally demonstrated an unknown key-share attack on Huang's protocol and proposed a more secure and efficient scheme [19] to eliminate the security flaws. However, Farash and Attari indicated that Tallapally's scheme was vulnerable to an undetectable online password guessing attack and insecure against an offline password guessing attack, and proposed an enhanced protocol [11]. In [9], Lu et al. observed that Farash and Attari's protocol was still insecure against an offline password guessing attack, and proposed a modified 3PAKE protocol for wireless communication (3WPAKE for short) without using smart cards. In [20], Chen et al. launched an offline password guessing attack on Lu et al.'s protocol, and proposed an enhanced version not preserving anonymity.

The contribution of this work is as follows. First, we point out the following weaknesses in the 3WPAKE protocol that are less feasible for healthcare support practical application: (1) 3WPAKE protocol does not achieve user anonymity or untraceability, and it is vulnerable to a privileged insider attack that causes impersonation attack. (2) As users in the 3WPAKE calculate exponentiation operations, it is inefficient for resource-constrained healthcare environments. Second, we develop a new secure biometric-based efficient password-authenticated key exchange (SBAKE) protocol and present the healthcare support wireless communication environment that is aimed to deploy the SBAKE protocol. To manage authorization and access to the server, we employ chaotic map and biometric verification, along with password verification. When chaos properties such as unpredictability are applied, there is an understanding of parameter sensitivity, e.g., of initial conditions, such that these properties satisfy the goal of efficiency, specifically, of being more computationally efficient than modular exponential computation and multiplication operations of an elliptic curve [21,22] and the essential properties of cryptography. Researchers have proposed security enhanced protocols [21,23–29] that use biological characteristics such as fingerprints or irises. A practical implementation is a fuzzy extractor for biometric key extraction. Fuzzy extractors have the advantage of protecting the biometric template by rendering its storage useless [30,31]. Their performance in terms of key entropy and key stability is consistently improved. Third, we prove that the proposed mechanism satisfies various security properties and provide formal security proofs using random oracle model and automated validation of internet security protocols and applications (AVISPA). Finally, we analyze that the SBAKE protocol performs better computational complexity and time consumption than other existing protocols. The high security and significantly low computation and communication costs of our protocol make it suitable for healthcare support PAKE protocols.

#### 2. Materials and Methods

This section introduces the cryptographic one-way hash function [29], Chebyshev chaotic map [32,33], fuzzy extractor [24,25,34], notations used in this paper, threat model, and security properties.

#### **Collision-Resistant one-way Hash Function**

**Definition 1.** A collision-resistant one-way hash function  $h : \{0,1\}^* \to \{0,1\}^n$  takes a random length binary string  $x \in \{0,1\}^*$  as an input and outputs a fixed n-bit binary string  $h(x) = \{0,1\}^n$ . The probability of an adversary A finding a collision is defined as

$$Adv_{A}^{HASH}(t) = \Pr[A(x, x') : x \neq x', h(x) = h(x')],$$
(1)

where  $\Pr[E]$  refers to the probability an event E occurring, and A(x, x') means that the pair (x, x') is chosen by A. In this case, the probability in the advantage is computed over that of the random choices made by A with execution time t. The hash function  $h(\cdot)$  is collision-resistant, if  $Adv_A^{HASH}(t) \le \varepsilon$  for sufficiently small  $\varepsilon > 0$ .

#### **Chebyshev Chaotic Map and its Properties**

Let *n* be an integer and *x* be a real number within the interval [-1, 1]. The Chebyshev polynomial of degree *n* is defined as  $T_n(x) = \cos(n \cdot \arccos(x))$ . With this equation, the recurrence relation  $T_n(x)$  is defined as  $T_n(x) = 2xT_{n-1}(x) - T_{n-2}(x)$ , where  $n \ge 2$ ,  $T_0(x) = 1$ ,  $T_1(x) = x$ , and satisfies the semigroup property:  $T_r(T_s(x)) = T_r(x) = T_s(T_r(x))$ . In order to improve security, Zhang [35] proved that the semigroup property holds for Chebyshev polynomials defined over the interval  $(-\infty, +\infty)$ . In this work, the enhanced Chebyshev polynomials are used:  $T_n(x) = 2xT_{n-1}(x) - T_{n-2}(x) \pmod{p}$ , where  $n \ge 2$ ,  $x \in (-\infty, +\infty)$ , and *p* is a large prime. They are subject to the following two problems.

**Definition 2.** Given x and y, the Chaotic Maps Discrete Logarithm Problem (CMDLP) is that finding an integer r such that  $y = T_r(x)$  is computationally infeasible. The probability of an adversary A being able to solve the CMDLP is defined as

$$Adv_A^{CMDLP}(t) = \Pr[A(x, y) = r : r \in Z_p^*, y = T_r(x) \pmod{p}].$$
(2)

**Definition 3.** Given x,  $T_r(x)$ , and  $T_s(x)$ , the Chaotic Map Diffie-Hellman Problem (CMDHP) is that calculating  $T_{rs}(x)$  is computationally infeasible.

#### **Fuzzy Extractor**

A fuzzy extractor extracts a string  $\sigma$  from its biometric input  $Bio_i$  in an error-tolerant way. This method was used in order to avoid the problem of bio-hash [30] and utilization of noisy biometrics. The fuzzy extractor method involves the following two operations:

Gen: This procedure is defined as  $\text{Gen}(Bio_i) = (\sigma_i, \tau_i)$ , where the biometric data  $Bio_i$  is the input of Gen, and it outputs an "extracted" secret key string  $\sigma_i \in \{0, 1\}^l$  of length l and an auxiliary public reproduction string  $\tau_i$ .

Rep: This procedure takes a noisy biometric  $Bio_i'$  and its corresponding string  $\tau_i$  as input, and if the Hamming distance between  $Bio_i$  and  $Bio_i'$  is less than the threshold *th*, the Rep procedure recovers the biometric key data  $\sigma_i$ : Rep( $Bio_i', \tau_i$ ) =  $\sigma_i$  if d( $Bio_i, Bio_i'$ ) < *th*.

If the input changes but remains close, the extracted  $\sigma_i$  remains the same. To assist in recovering  $\sigma_i$  from  $Bio_i'$ , a fuzzy extractor outputs a public string  $\tau_i$ . The extracted key  $\sigma_i$  from  $Bio_i$  by a fuzzy extractor can be used as a key in any cryptographic application, but, unlike traditional keys, need not be stored because it can be recovered from any  $Bio_i'$  close to  $Bio_i$ .

#### Notations

The notations used throughout this paper are listed in Table 1.

Not	ation	Description				
<b>3WPAKE</b>	SBAKE					
$U_A, U_B$	$U_A, U_B$	Communication parties user <i>A</i> and user <i>B</i>				
S	S	Server				
$ID_A$ , $ID_B$	$ID_A, ID_B$	IDs of user A and user B				
$pw_A, pw_B$	$pw_A, pw_B$	Passwords of user <i>A</i> and user <i>B</i>				
p, q	p	Large prime numbers				
$Z_p$	$Z_p$	Ring of integer modulo p				
$Z_p^*$	$Z_p^*$	The multiplicative group of non-zero integers modulo <i>p</i>				
g	-	A generator of G ( $\subseteq Z_p^*$ )				
$h(\cdot)$	$h_1(\cdot)$	One-way hash function $h_1:\{0,1\}^* \rightarrow \{0,1\}^l$				
-	$h_2(\cdot)$	One-way hash function $h_2:[-1, 1] \rightarrow \{0, 1\}^l$				
-	$y_A, y_B$	Random numbers selected by server <i>S</i>				
$r_{A_i}$	d	Random numbers selected by user A				
$r_{B_i}$	k	Random numbers selected by user <i>B</i>				
<i>x, y, z</i>	-	Random exponents selected by user A, user B, and server S, respectively				
-	S	Secret master key selected by server S				
$H_A$ , $V_A$ , $W_A$ , $R_A$	$f_A, C_A, W_A, Y_A, \alpha_A$	Authentication parameters of user A				
$H_B, V_B, W_B, R_B$	$f_B, C_B, W_B, Y_B, \alpha_B$	Authentication parameters of user <i>B</i>				
$N_s, T_A, T_B$	$P_A, P_B, Q_A, Q_B$	Authentication parameters of server S				
K <sub>SA</sub> , K <sub>SB</sub>	$S_A, S_B$	Server $S$ 's keys used to authenticate user $A$ and user $B$				
$K_{AS}$ , $K_{BS}$	-	User's keys used to authenticate the server <i>S</i>				
$Auth_{A_{i}}Auth_{B}$	$Auth_{A_{i}}Auth_{B}$	Computed user's parameters used to authenticate user A and user $B$				
$Q_{A'}Q_B$	$V_A, V_B, I_A, I_B,$	Computed server's parameters for user A and user B				
sk	sk	Session key shared with user $A$ and user $B$				
⊕,∥	⊕,∥	Exclusive-or and concatenation operation				
-	$Bio_A$ , $Bio_B$	Biometric data of user A and user B				
-	Gen, Rep	Fuzzy generator and reproduction procedure, respectively				
-	$\sigma_A, \sigma_B$	Biometric secret key of user A and user B				
-	$ au_A$ , $ au_B$	Biometric public reproduction parameter of user $A$ and user $B$				
-	th	Error tolerance threshold used by fuzzy extractor				
-	$T_n(.)$	Chebyshev polynomial of degree <i>n</i>				

Table 1. Notations used in this paper and 3WPAKE.

Abbreviations: SBAKE, secure biometric-based efficient password-authenticated key exchange; 3WPAKE, three-party password-authenticated key exchange for wireless communication.

#### **Threat Model**

We introduce the following security assumptions [16] regarding the capabilities of the probabilistic polynomial-time adversary A to achieve the security properties of the 3PAKE protocols for wireless communications.

- *A* can eavesdrop, insert, intercept, alter, and delete messages exchanged among the protocol, user  $U_A$ , user  $U_B$ , and the server *S*.
- *A* may be a legitimate protocol participant (an insider), an external party (an outsider), or some combination of the two.

#### **Security Requirements**

A secure 3PAKE protocol with mutual anonymity in wireless communication should satisfy the following requirements [36,37]:

- User anonymity: Even if an adversary eavesdrops on the messages transmitted in the communication parties, the user's identity should be protected.
- Mutual authentication: Two partnering users and the server can authenticate one another.
- Session key security: No one except for those who are partnered can establish the session key.
- Known-key security: When a particular session key is lost, it does not reveal the other session keys.
- Forward secrecy: Even if a user's password is compromised, it does not reveal past session keys or the new password.
- Robustness: The protocol should withstand various types of attacks, such as offline password guessing, replay, insider, and impersonation.

#### 3. Results

In this section, we analyze why the 3WPAKE does not achieve anonymity or untraceability, and why it is vulnerable to privileged insider attack that causes impersonation attacks. Moreover, as users in and the 3WPAKE protocol calculate exponentiation operations, it is inefficient for resource-constrained healthcare mobile environments. The details are as follows.

#### 3.1. Revisit of 3WPAKE Protocol

Before we explain the issue of failure to achieve privacy and other security properties, this section revisits the 3WPAKE protocol.

Step 1.  $U_A$  randomly selects  $x, r_A \in Z_p^*$ , computes  $H_A = h(pw_A) \oplus r_A$ ,  $V_A = h(pw_A || r_A || ID_A)$ ,  $R_A = g^x \oplus V_A \pmod{q}$ , and sends  $M_{A1} = \{H_A, V_A, R_A, ID_A\}$  to S. Similarly,  $U_B$  sends  $M_{B1} = \{H_B, V_B, R_B, ID_B\}$  to S.

Step 2. With the received messages  $M_{A1}$  and  $M_{B1}$ , S computes  $r_A$ ,  $r_B \in Z_p^*$  using the known passwords  $pw_A$  and  $pw_B$ , and checks whether or not the received  $V_A$  and  $V_B$  are equal to  $h(pw_A || r_A || ID_A)$  and  $h(pw_B || r_B || ID_B)$ , respectively. Then, S computes  $R_A' = R_A \oplus h(pw_A || r_A || ID_A)$  and  $R_B' = R_B \oplus h(pw_B || r_B || ID_B)$ , chooses a random number  $z \in Z_p^*$  and computes  $N_S = g^z \pmod{q}$ ,  $K_{sa} = (R_A')^z \pmod{q}$ ,  $K_{sB} = (R_B')^z \pmod{q}$ ,  $T_A = h(pw_A || r_A || K_{SA} || ID_A)$ ,  $T_B = h(pw_B || r_B || K_{SB} || ID_B)$ . After that, S sends the messages  $M_{SA1} = \{T_A, ID_B, N_S\}$  to  $U_A$  and  $M_{SB1} = \{T_B, ID_A, N_S\}$  to  $U_B$ .

Step 3. With the received message  $M_{SA1}$ ,  $U_A$  computes  $K_{AS} = (N_S)^x \pmod{q}$ , checks whether or not the received  $T_A$  is equal to  $h(pw_A \parallel r_A \parallel K_{AS} \parallel ID_A)$ , then computes  $W_A = h(ID_A \parallel ID_B \parallel K_{AS} \parallel pw_A \parallel r_A)$ , sends  $M_{A2} = \{ID_A, W_A\}$  to *S*. Simultaneously, with the received message  $M_{SB1}$ ,  $U_B$  sends  $M_{B2} = \{ID_B, W_B\}$  to *S*.

Step 4. With the received messages  $M_{A2}$  and  $M_{B2}$ , S checks whether or not  $W_A = h(ID_A || ID_B || K_{SA} || pw_A || r_A)$  and  $W_B = h(ID_A || ID_B || K_{SB} || pw_B || r_B)$ , computes  $Q_A = K_{SB} \oplus h(ID_A || ID_B || K_{SA} || pw_A || r_A)$  and  $Q_B = K_{SA} \oplus h(ID_A || ID_B || K_{SB} || pw_B || r_B)$ . Then, S sends  $Q_A$  to  $U_A$  and  $Q_B$  to  $U_B$ .

Step 5. With the received message  $Q_A$ ,  $U_A$  computes  $K_{SB} = Q_A \oplus h(U_A || U_B || K_{SA} || pw_A || r_A)$ ,  $sk = (K_{SB})^x \pmod{q}$ ,  $Auth_A = h(sk || ID_A || ID_B)$ , sends  $Auth_A$  to  $U_B$ . With the received message  $Q_B$ ,  $U_B$  sends  $Auth_B$  to  $U_A$ .

Step 6. With the received  $Auth_A$  and  $Auth_B$ ,  $U_A$  and  $U_B$  evaluate the correctness of  $Auth_A$  and  $Auth_B$ , then agree on the session key  $sk = g^{xyz}$ .

#### 3.2. Security Analysis of 3WPAKE Protocol

Violating anonymity: An authentication protocol could provide user anonymity if no adversary can compromise the user's identity by launching active or passive attacks in any phase [21]. In the 3WPAKE protocol, messages  $M_{A1}$ ,  $M_{B1}$ ,  $M_{SA1}$ ,  $M_{SB1}$ ,  $M_{A2}$ , and  $M_{B2}$  include plain text information about the  $U_A$  and  $U_B$ , so an adversary can easily acquire communication entities for sending and receiving messages through eavesdropping on the communication channel. This violates the preservation of user anonymity (privacy), which is a basic property of the authentication protocol.

Violating untraceability: User untraceability means that an adversary cannot identify any previous sessions involving the same user. In the 3WPAKE protocol, messages  $M_{A1}$ ,  $M_{B1}$ ,  $M_{SA1}$ ,  $M_{SB1}$ ,  $M_{A2}$ , and  $M_{B2}$  include plain text information about the  $U_A$  and  $U_B$  so that an adversary can easily acquire communication entities for sending and receiving messages through eavesdropping on the communication channel. This violates the preservation of user untraceability, which is a basic property of an authentication protocol.

Vulnerability to privileged insider attack: Authenticated principals acting maliciously form the basis of a powerful attacking model. This model has been used by other researchers such as Bellare and Rogaway [38], who assumed that the adversary can corrupt any principal at any time. It was pointed out by Gollmann [39] that this corresponds to the most realistic situation in commercial applications, where most real-world attacks come from insiders. A privileged insider attack occurs

when an administrator can access a user's password so as to impersonate that user. In Step 2 of the 3WPAKE protocol, *S* knows  $U_A$  and  $U_B$ 's identities and passwords; so as malicious *S* can easily conduct a privileged insider attack as follows.

**1.** Malicious *S* selects  $x, r_A \in Z_p^*$  imitating  $U_A$ , computes  $R_A = g^* \oplus h(pw_A || r_A || ID_A)$ ,  $K_{SA} = (R_A)^z$ ,  $Q_B = K_{SA} \oplus h(ID_A || ID_B || K_{SB} || pw_B || r_B)$ , and sends  $Q_B$  to  $U_B$  in Step 4 of the 3WPAKE protocol.

**2.** Malicious *S* can compute the session key  $sk = (K_{SB})^x$ ,  $Auth_A = h(sk \parallel ID_A \parallel ID_B)$ , then sends  $Auth_A$  and  $ID_A$  to  $U_B$ .

Therefore, malicious *S* easily impersonates  $U_A$ , and shares a session key *sk* with  $U_B$ , without any authentication problem. The session key should be computed only by the intended parties like  $U_A$  and  $U_B$ , and not by *S*. A secure authenticated key exchange protocol should block the malicious *S* impersonating any legal user. This vulnerability may cause security risks in a real situation, like the IoT environment. We must modify the 3WPAKE protocol such that no malicious inside attacker can impersonate any legal user.

Vulnerability to replay attack: Suppose an adversary *A* records the login request message  $M_{A1}$  and resends it to *S*, then *S* computes  $r_A$ ,  $V_A$ ,  $R_A'$ ,  $N_S$ ,  $K_{SA}$ ,  $T_A$ , and sends a response message  $M_{SA1}$  to  $U_A$  without recognizing that the login request message was old and had been sent again. In the 3WPAKE protocol, *S* cannot distinguish between old login request messages and fresh login request messages. Even if *A* cannot compute the session key, this vulnerability may be exploited by an adversary, leading to a waste of system resources that can threaten the entire system.

Inefficient authentication phase: Lu et al. [9] assume open access to wireless services for wireless communications using various portable devices (mobile phones, laptops, USB thumb drives, and PDAs). Efficiency is crucial for resource-constrained portable devices. In the 3WPAKE protocol,  $U_A$  and  $U_B$  compute exponentiation operations in Step 1, 3, and 5 in the previous section, which exhausts resource-constrained devices. We need to improve efficiency in order to satisfy the need for secure/private access to services via wireless communication networks.

#### 3.3. The SBAKE Protocol

This section demonstrates our SBAKE protocol, which fixes the vulnerabilities of the 3WPAKE protocol by applying biometric data and adopting a chaotic map that is much more efficient than performing point multiplication operations of the elliptic curve [21]. Figure 1 presents the healthcare support wireless communication environment that is aimed to deploy the SBAKE protocol, where users can be patients and staff can be doctors, pharmacists, or the medical billing center. Users and staff register to the server, then perform the login and authentication phase. The data of user is collected using IoTs and transferred to the server, which is able to store and process a huge amount of data. The data is accessible to the staff of the healthcare organization, then the staff can provide health services to the users. We assume that the following information has been pre-established in the registration phase. In order to compute message size, based on [16], we set both the block size of one-way hash function  $h_1(.), h_2(.)$ , and Chebyshev chaotic map to a length of 20 bytes; identities  $ID_A, ID_B$ , and passwords  $pw_A, pw_B$  to 8 bytes, and the random numbers *d* and *k* to 16 bytes in length.

Figure 1. Healthcare support wireless communication environment in the SBAKE protocol.

**Registration phase:** By performing the following steps (Figure 2a), a new  $U_A$  registers to S.

$U_A$	S	$U_A$

(**c**)

**Figure 2.** (a) Registration phase; (b) Password and biometric update; (c) Login and authentication phase of SBAKE protocol.

Step 1.  $U_A$  selects  $ID_A$ ,  $pw_A$ , and inputs biometric  $Bio_A$  in  $U_A$ 's mobile device.  $U_A$  extracts  $\sigma_A$  and  $\tau_A$  as  $Gen(Bio_A) = (\sigma_A, \tau_A)$  by applying a Fuzzy extractor on  $Bio_A$ , computes  $h_1(pw_A || \sigma_A)$ , and sends  $\{ID_A, h_1(pw_A || \sigma_A)\}$  to *S* via a secure channel.

Step 2. With the received information from  $U_A$ , S randomly selects  $y_A$ , computes  $V_A = h_1(y_A || s) \oplus h_1(s)$ ,  $S_A = h_1(ID_A || s) \oplus h_1(pw_A || \sigma_A)$ ,  $I_A = ID_A \oplus h_1(y_A || s)$ , stores  $\{S_A, I_A, h_1(y_A || s)\}$  in its database, and sends  $\{S_A, V_A\}$  to  $U_A$  via a secure channel.

 $U_A$  computes  $f_A = h_1(ID_A \oplus pw_A \oplus \sigma_A)$ , and stores  $\{f_A, \tau_A, S_A, V_A, \text{Gen, Rep}\}$  in  $U_A$ 's mobile device.

**Login and authentication phase:** By performing the following steps (Figure 2c),  $U_A$  and  $U_B$  login to *S*, authenticate each other, and securely share a session key.

Step 1.  $U_A$  inputs  $ID_A$ ,  $pw_A$ ,  $Bio_A'$ , and computes  $\sigma_A^* = \operatorname{Rep}(Bio_A', \tau_A)$ ,  $f_A^* = h_1(ID_A \oplus pw_A \oplus \sigma_A^*)$ . If  $f_A^* \neq f_A$ , then the process aborts, otherwise  $(U_A, pw_A, \text{ and } \sigma_A \text{ are approved}) U_A$  randomly generates  $d \in Zp^*$  and computes  $C_A = ID_A \oplus T_d(x)$ ,  $W_A = S_A \oplus h_1(pw_A || \sigma_A) = h_1(ID_A || s)$ ,  $Y_A = W_A \oplus C_A \oplus ID_B$ ,  $\alpha_A = h_1(ID_A || C_A || W_A)$ . Then  $U_A$  sends  $M_{A1} = \{C_A, Y_A, \alpha_A, V_A\}$  to S. Similarly,  $U_B$  inputs  $ID_B$ ,  $pw_B$ , *Bio*<sub>B</sub>, and computes  $\sigma_B^* = \text{Rep}(Bio_B, \tau_B), f_B^* = h_1(ID_B \oplus pw_B \oplus \sigma_B^*)$ . If  $f_B^* \neq f_B$ , then the process aborts, otherwise  $U_B$  randomly generates  $k \in Z_p^*$  and computes  $C_B = ID_B \oplus T_k(x), W_B = S_B \oplus h_1(pw_B || \sigma_B) = h_1(ID_B || s), Y_B = W_B \oplus C_B \oplus ID_A, \alpha_B = h_1(ID_B || C_B || W_B)$ . Then  $U_B$  sends  $M_{B1} = \{C_B, Y_B, \alpha_B, V_B\}$  to S.

Step 2. When receiving messages  $M_{A1}$  and  $M_{B1}$ , S computes  $h_1(y_A || s) = V_A \oplus h_1(s)$  using its secret master key s, derives  $ID_A = I_A \oplus h_1(y_A || s)$ ,  $T_d(x) = C_A \oplus ID_A$ , and  $W_A = h_1(ID_A || s)$ , similarly,  $h_1(y_B || s) = V_B \oplus h_1(s)$ ,  $T_k(x) = C_B \oplus ID_B$ , and  $W_B = h_1(ID_B || s)$ . Then, S checks whether or not the received  $\alpha_A$  and  $\alpha_B$  are equal to  $h_1(ID_A || C_A || W_A)$  and  $h_1(ID_B || C_B || W_B)$ , respectively. Then, S derives  $Y_A \oplus W_A \oplus C_A = ID_B$ ,  $Y_B \oplus W_B \oplus C_B = ID_A$ , so S acquires communication partners, then computes  $P_A = h_1(h_1(pw_A || \sigma_A) || T_d(x) || ID_A || ID_B)$ ,  $Q_A = T_k(x) \oplus ID_A$ , similarly,  $P_B = h_1(h_1(pw_B || \sigma_B) || T_k(x) || ID_B || ID_A)$ ,  $Q_B = T_d(x) \oplus ID_B$ , and sends  $M_{A2} = \{P_A, Q_A\}$  to  $U_A$  and  $M_{B2} = \{P_B, Q_B\}$  to  $U_B$ .

Step 3. With the received  $M_{A2}$ ,  $U_A$  checks whether or not  $P_A$  is equal to  $h_1(h_1(pw_A || \sigma_A) || T_d(x) ||$  $ID_A || ID_B)$ , and derives  $T_k(x) = Q_A \oplus ID_A$ , computes  $sk = h_2(T_d(x), T_k(x), T_{dk}(x))$  and  $Auth_A = h_1(sk || T_k(x))$ . Then,  $U_A$  sends  $Auth_A$  to  $U_B$ . Similarly, with the received  $M_{B2}$ ,  $U_B$  checks whether or not  $P_B$  is equal to  $h_1(h_1(pw_B || \sigma_B) || T_k(x) || ID_B || ID_A)$ , and derives  $T_d(x) = Q_B \oplus ID_B$ , computes  $sk = h_2(T_d(x), T_k(x), T_{dk}(x))$  and  $Auth_B = h_1(sk || T_d(x))$ . Then,  $U_B$  sends  $Auth_B$  to  $U_A$ . Finally,  $U_A$  and  $U_B$  agree on the session key  $sk = h_2(T_d(x), T_{dk}(x))$ .

Based on the above descriptions, in the login and authentication phase, the message size of the  $\{C_A, Y_A, \alpha_A, V_A\}$ ,  $\{C_B, Y_B, \alpha_B, V_B\}$ ,  $\{P_A, Q_A\}$ ,  $\{P_B, Q_B\}$ ,  $Auth_A$ , and  $Auth_B$  can be computed as (20 + 20 + 20 + 20) = 80 bytes, (20 + 20 + 20) = 80 bytes, (20 + 20 + 20) = 80 bytes, (20 + 20) = 40 bytes, (20 + 20)

**Password and biometric update:** If  $U_A$  intends to update his/her password and biometric data,  $U_A$  inputs old information { $ID_A$ ,  $pw_A^{old}$ ,  $Bio_A^{old}$ } in the  $U_A$ 's mobile device, and computes  $\sigma_A^{old} =$ Rep( $Bio_A^{old}$ ,  $\tau_A^{old}$ ),  $f_A^{old} = h_1(ID_A \oplus pw_A^{old} \oplus \sigma_A^{old})$ . If  $f_A^{old} \neq f_A$ , then terminates the connection. Otherwise,  $U_A$  inputs new password  $pw_A^{new}$  and new biometric data  $Bio_A^{new}$  in the  $U_A$ 's mobile device, and computes  $Gen(Bio_A^{new}) = (\sigma_A^{new}, \tau_A^{new})$ ,  $f_A^{new} = h_1(ID_A \oplus pw_A^{new} \oplus \sigma_A^{new})$ ,  $S_A^{new} = S_A^{old}$   $\oplus h_1(pw_A^{old} || \sigma_A^{old}) \oplus h_1(pw_A^{new} || \sigma_A^{new})$  then replaces { $f_A^{old}$ ,  $\tau_A^{old}$ ,  $S_A^{old}$ } with { $f_A^{new}$ ,  $\tau_A^{new}$ ,  $S_A^{new}$ } into the  $U_A$ 's mobile device (Figure 2b).

#### 3.4. Security Analysis and Proof of SBAKE Protocol

This section presents the security analysis of the SBAKE protocol.

#### 3.4.1. Simulation using AVISPA

We simulate the SBAKE protocol for formal analysis using the widely accepted simulation tool named AVISPA. The main contribution of this simulation is verifying whether the SBAKE protocol is secure of two attacks, i.e., man-in-the-middle attack and replay attack. This simulation tool is composed of four back-ends: (1) On-the-fly Model-Checker; (2) Constraint-Logic-based Attack Searcher; (3) SAT-based Model Checker; and (4) Tree Automata based on Automatic Approximations or the Analysis of Security Protocols [40].

The SBAKE protocol is implemented in High Level Protocol Specification Language (HLPSL) [41] in AVISPA. The role of  $U_A$  is shown in Table 2a.  $U_A$  first receives the start signal, then renews its state value from 0 to 1. This value is retained by the variable state. In a similar way, the roles of  $U_B$  and *S* of the SBAKE protocol are described in Table 2b,c, respectively. The roles of the session, goal, and environment are described in Table 2d. The simulation result of the SBAKE protocol using CL-AtSe is shown in Table 3. The result shows that the SBAKE protocol is secure of two attacks: replay and man-in-the-middle attacks.

<b>Table 2.</b> Role specification for ( <b>a</b> ) user $U_A$ , ( <b>b</b> ) use	er $U_B$ , (c) user $S$ , (d) session, goal, and environment.

#### 3.4.2. Formal Security Proof

This subsection describes the formal security analysis of the SBAKE using the random oracle model and demonstrates that the protocol is secure. First, we recall Definition 1 of collision resistant one-way hash function in the preliminaries section.

**Theorem 1.** Under the assumption that the collision-resistant one-way hash function  $h(\cdot)$  closely behaves like an oracle, then the SBAKE is provably secure against an adversary A for the protection of a user  $U_A$ 's personal information including the identity  $ID_A$ , password  $pw_A$  and biometric key  $\sigma_A$  of the user  $U_A$ , secret master key s that is selected by S, a shared secret key  $S_A$  between the  $U_A$  and S, and the session key sk between users  $U_A$ and  $U_B$ .

**Proof.** The formal proof of the SBAKE protocol is similar to those shown in [41–43]. Using the following oracle model to construct an *A* that will have the ability to derive  $U_A$ 's identity  $ID_A$ , password  $pw_A$ , biometric key  $\sigma_A$ , the secret master key *s* that is selected by *S*, the shared session key *sk* between  $U_A$  and  $U_B$ , and the shared secret key  $S_A$  between  $U_A$  and *S*.

Reveal: This random oracle will unconditionally output the input *x* from given hash result y = h(x). Now, an adversary *A* runs the experimental algorithm shown in Algorithm 1,  $EXP_{HASH,A}^{SBAKE}$  for the SBAKE protocol. We define the success probability for  $EXP_{HASH,A}^{SBAKE}$  as  $Success_{BAKE}^{SBAKE} = |\Pr[EXP_{HASH,A}^{SBAKE} = 1] - 1|$ . The advantage function for this experiment becomes  $Adv_{HASH,A}^{SBAKE}(t, q_R) = max_A \{Success_{HASH,A}^{SBAKE}\}$ , where the maximum is taken over all of *A* with execution time *t* and the number of queries  $q_R$  made to the Reveal oracle. Considering the experiment presented in Algorithm 1, we acquire that if there exists a Reveal oracle that can invert  $h_1(.)$  and  $h_2(.)$ , then *A* could directly derive  $U_A$ 's identity  $ID_A$ , password  $pw_A$ , biometric key  $\sigma_A$ , the secret master key *s* selected by *S*, shared session key *sk*, and the shared secret key  $S_A$  between the  $U_A$  and *S*. In this case, *A* will discover the complete connections between  $U_A$  and *S*; however, it is computationally infeasible to invert a one-way hash function  $h(\cdot)$ , i.e.,  $Adv_{HASH,A}^{SBAKE}(t) \le \varepsilon$ ,  $\forall \varepsilon > 0$ . Then, we have  $Adv_{HASH,A}^{SBAKE}(t, q_R) \le \varepsilon$  since  $Adv_{HASH,A}^{SBAKE}(t, q_R)$  depends on  $Adv_{HASH,A}^{SBAKE}(t)$ . Therefore, the SBAKE protocol is provably secure against adversaries for deriving  $\{ID_A, pw_A, Bio_A, s, S_A, sk\}$ . Deriving  $\{ID_B, pw_B, Bio_B, S_B\}$  shows a similar phenomenon, so we omit the description here. Hence, the theorem is proven.  $\Box$ 

#### 3.4.3. Informal Security Proof

This subsection examines that the SBAKE protocol is resistant against various known attacks and achieves the basic security properties described in the preliminaries section. Figure 3a compares the security attributes among the SBAKE and other existing protocols.

SA1. Anonymity: Assume that an adversary *A* intercepts communication messages  $M_{A1}$ ,  $M_{B1}$ ,  $M_{SA1}$ ,  $M_{SB1}$ ,  $Auth_A$ ,  $Auth_B$  during the login and authentication phase, then  $ID_A$  and  $ID_B$  cannot be derived from { $C_A$ ,  $Q_A$ } and { $C_B$ ,  $Q_B$ } without knowing the random numbers *d* and *k* selected by communicating users  $U_A$  and  $U_B$ , respectively. Moreover, because of the one-way hash function,  $ID_A$  and  $ID_B$  cannot be derived from { $\alpha_A$ ,  $P_A$ }, and { $\alpha_B$ ,  $P_B$ }. Therefore, the SBAKE protocol provides user anonymity.

SA2. Untraceability: The messages { $C_A Y_A$ ,  $\alpha_A$ } and { $P_A$ ,  $Q_A$ ,  $Auth_A$ } sent during the login and authentication phase are changed dynamically in each session. Since  $U_A$  generates a random number d and computes  $T_d(x)$  in each session, messages { $C_A Y_A$ ,  $\alpha_A$ } and { $P_A$ ,  $Q_i$ ,  $Auth_A$ } differ from the messages in the previous sessions. Therefore, the SBAKE protocol provides user untraceability.

#### Algorithm 1: Algorithm EXP<sup>SBAKE</sup> HASH,A

Eavesdrop login request message  $\{C_A, Y_A, \alpha_A, V_A\}$ Call the Reveal oracle. Let  $(ID_A', C_A', W_A') \leftarrow \text{Reveal}(\alpha_A)$ Call the Reveal oracle. **Figure 3.** (a) SA1: provide anonymity, SA2: provide untraceability, SA3: provide mutual authentication, SA4: resist privileged insider attack, SA5: provide session key secrecy, SA6: resist offline password guessing attack, SA7: provide perfect forward secrecy,  $\sqrt{}$ : yes, x: no; (b) performance comparison between SBAKE and existing other protocols.

SA3. Mutual authentication: In the SBAKE protocol, when the message  $M_{A1} = \{C_A, Y_A, \alpha_A, V_A\}$  is received from  $U_A$ , S computes  $h_1(y_A || s) = V_A \oplus h_1(s)$  using its secret master key s and derives  $ID_A = I_A$  $\oplus h_1(y_A || s)$ . S computes  $W_A = h_1(ID_A || s)$  and  $\alpha_A' = h_1(ID_A || C_A || W_A)$ , then checks whether or not the received  $\alpha_A$  is equal to  $\alpha_A'$ . If this is indeed the case,  $U_A$  is authenticated.  $U_A$  authenticates S by checking the verification of  $P_A$ . Finally, the authentication between  $U_A$  and  $U_B$  is completed through the correctness of  $Auth_B$  and  $Auth_A$ , which are only available to themselves.

SA4. Privileged insider attack: In the registration phase of the SBAKE protocol,  $U_A$  sends a registration message { $ID_A$ ,  $h_1(pw_A \parallel \sigma_A)$ } to *S* via a secure channel. The  $pw_A$  is protected under the one-way hash function  $h_1(\cdot)$  and the biometric key  $\sigma_A$ . Thus, guessing a password  $pw_A$  from  $h_1(pw_A \parallel \sigma_A)$  is computationally infeasible. Therefore, the SBAKE protocol is secure against privileged insider attacks.

SA5. Session key security: Suppose that adversary *A* intercepts all of the messages { $C_A$ ,  $Y_A$ ,  $\alpha_A$ ,  $V_A$ ,  $P_A$ ,  $Q_A$ ,  $Auth_A$ } and { $C_B$ ,  $Y_B$ ,  $\alpha_B$ ,  $V_B$ ,  $P_B$ ,  $Q_B$ ,  $Auth_B$ } that are transmitted via public channel among  $U_A$ ,  $U_B$ , and *S*, steals the mobile devices of  $U_A$  and  $U_B$ , then extracts all information { $f_A$ ,  $f_B$ ,  $\tau_A$ ,  $\tau_B$ ,  $S_A$ ,  $S_B$ ,  $V_A$ ,  $V_B$ , Gen, Rep}; however, *A* cannot compute the session key  $sk = h_2(T_d(x), T_k(x), T_{dk}(x))$ . Even if *A* obtains  $T_d(x)$  and  $T_k(x)$ , *A* is required to solve the CMDLP for computing the  $sk = h_2(T_d(x), T_{k(x)})$ ,  $T_{k(x)}$ ,  $T_{dk}(x)$ ]. In order to compute  $T_d(x)$  and  $T_k(x)$  from { $C_A$ ,  $Q_A$ } and { $C_B$ ,  $Q_B$ },  $ID_A$  and  $ID_B$  are needed, respectively. In order to retrieve  $ID_A$  and  $ID_B$  from { $C_A$ ,  $Q_A$ } and { $C_B$ ,  $Q_B$ }, *A* needs to know  $T_d(x)$  and  $T_k(x)$ , respectively. Without knowing *d* and *k*, which are selected randomly by communicating with users  $U_A$  and  $U_B$ , respectively, *A* cannot obtain  $T_d(x)$  and  $T_k(x)$ . Moreover, computing  $T_{dk}(x)$  from  $T_d(x)$  and  $T_k(x)$  is required if one wants to obtain the session key, then one will be required to solve the CMDHP. Therefore, the SBAKE protocol provides session key security.

SA6. Offline password guessing attack: Assume that adversary *A* steals the mobile device of  $U_A$  and extracts all of the information stored in the device. This information includes { $f_A$ ,  $\tau_A$ ,  $S_A$ ,  $V_A$ , Gen, Rep} that  $f_A = h(ID_A \oplus pw_A \oplus \sigma_A)$ ,  $S_A = h(ID_A || s) \oplus h(pw_A || \sigma_A)$ . The  $ID_A$  and  $pw_A$  are protected by one-way hash function  $h_1(\cdot)$  by the secret parameter including the server's secret master key *s* and secret biometric  $\sigma_A$ , so guessing the  $ID_A$  and  $pw_A$  is computationally infeasible without knowing the biometric  $Bio_A$  of  $U_A$  and the server's master secret key *s*. Moreover,  $U_A$ 's  $ID_A$  and  $pw_A$  are not sent during the communication; so the SBAKE protocol is resistant against offline password guessing attacks.

SA7. Perfect forward secrecy: In the SBAKE protocol, even if adversary *A* obtains  $U_A$  and  $U_B$  's  $\{pw_A, pw_B\}$  or *S*'s secret master key *s*, he/she cannot compute the previous session keys. In order to compute previous session key *sk*, *A* has to know the random numbers *d* and *k* generated by  $U_A$  and  $U_B$ . First, *A* cannot obtain the user's identity from the login and authentication information  $\{C_A, Y_A, \alpha_A, V_A, P_A, Q_A, Auth_A\}$  and  $\{C_B, Y_B, \alpha_B, V_B, P_B, Q_B, Auth_B\}$ , and even if *A* obtains  $T_d(x)$  and  $T_k(x)$ , *A* is required to solve the CMDHP in order to compute the *sk* =  $h_2(T_d(x), T_k(x), T_{dk}(x))$ . Because of CMDLP, it is infeasible to find *d* or *k* from  $T_d(x)$  and  $T_k(x)$ , and the random numbers  $\{d, k\}$  are different for each session. Therefore, the SBAKE protocol provides perfect forward secrecy.

## 4. Discussion

This section presents a comparison made between the SBAKE protocol and the other existing protocols [9,11,19,20,44–46] for the computation and communication complexities that express the superiority of the SBAKE efficiency. In Table 4, the performance comparison is made for the total computation cost measured by each operation's computation complexity, and the communication cost is measured by numbers and the length of a message exchange among entities. For the computation complexity comparison, the definitions of  $T_H$ ,  $T_{ECC}$ ,  $T_{EXP}$ ,  $T_{CCM}$ , and  $T_{FE}$  are the time complexity of a one-way cryptographic hash function, an elliptic curve point multiplication, a modular exponentiation, a Chebyshev chaotic map, and a fuzzy extractor operation used in biometric verification, respectively.

As shown in Table 4, we observed that SBAKE, 3WPAKE, Chen et al. [20], Xie et al. [44], Farash and Attari [11], Tallapally [19], Wu et al. [45], Chang et al. [46] protocols require the computation

complexities of  $21T_H + 4T_{CCM} + 2T_{FE}$ ,  $20T_H + 9T_{EXP}$ ,  $16T_H + 10T_{EXP}$ ,  $12T_H + 10T_{CCM}$ ,  $18T_H + 9T_{EXP}$ ,  $15T_H + 6T_{EXP}$ ,  $12T_H + 10T_{ECC}$ , and  $14T_H + 10T_{EXP}$ , respectively. According to Chatterjee et al. [28] and Wazid et al. [29], the running times of different cryptographic operations are as follows, on average  $T_H$  is 0.0005 s,  $T_{ECC}$  is 0.063075 s,  $T_{CCM}$  is 0.02102 s, and  $T_{FE}$  is nearly 0.063075 s. In addition,  $T_{EXP}$  approximates  $240T_H$  [33]. Hence, the result of computation complexity indicates that the SBAKE protocol is more efficient in contrast to 3WPAKE, Chen et al., Xie et al., Farash and Attari, Tallapally, Wu et al., Chang et al.'s protocols.

Table 4. Performance comparison for the login and authentication phase.

For the communication complexity comparison, we set the block size of one-way hash function  $h_1(.)$ ,  $h_2(.)$ , Chebyshev chaotic map, and elliptic curve point are 20 bytes long, and the modular exponentiation to be 128 bytes long. As shown in Figure 3b, the SBAKE protocol exchanged the least number of messages and had a lower communication load than 3WPAKE, Chen et al. [20], Farash and Attari [11], Tallapally [19], Wu et al. [45], Chang et al. [46]'s protocol, but a slightly increased communication load compared to Xie et al.'s protocol [44] that might be acceptable for security purposes. In short, the SBAKE protocol outperforms when considering computation and communication complexity, as illustrated in Table 4 and Figure 3b.

### 5. Conclusions

The role of innovative technologies like AI and blockchain in the healthcare system is expected in the future, the system has to be uncompromised and complete. In this work, we analyzed the security of the 3WPAKE protocol and determined the protocol to be vulnerable to privileged insider attacks, to not preserve privacy, and to have inefficient authentication verification. Furthermore, we proposed a SBAKE that fixes the security flaws of 3WPAKE and substantially improves efficiency. Our security and performance comparison implies that the SBAKE protocol achieves both better security and higher efficiency for healthcare support deployment. This is a meaningful conclusion, proposing a SBAKE protocol that is more lightweight and secure than the former protocol.

**Author Contributions:** Conceptualization, M.K.; validation, D.W.; formal analysis, M.K. and J.M.; writing-original draft, review and editing, M.K.; supervision, N.P. All authors have read and agreed to the published version of the manuscript.

**Funding:** This work was supported by Institute for Information & communications Technology Promotion (IITP), grant funded by the Korea government (MSIT) [2019-0-00203, The Development of Predictive Visual Security Technology for Preemptive Threat Response]. This work was supported by the Ministry of Education of the Republic of Korea and the National Research Foundation of Korea (NRF-2019S1A5C2A04083374).

Conflicts of Interest: The authors declare no conflict of interest.
