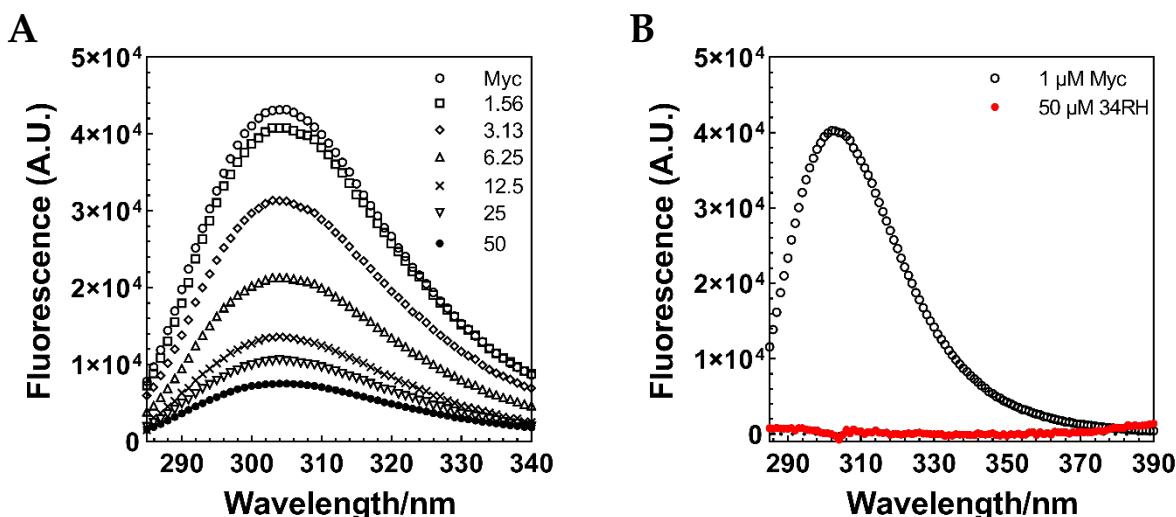

**Fig S1.** Myc, MaxRH, MaxRH-Y115F/Y123F (denoted as MaxRH\* in figure), P22 Max, and P21 Max constructs aligned using CLUSTAL O (1.2.4) multiple sequence alignment. Lowercase letters denote non-native residues remaining after TEV cleavage [63].

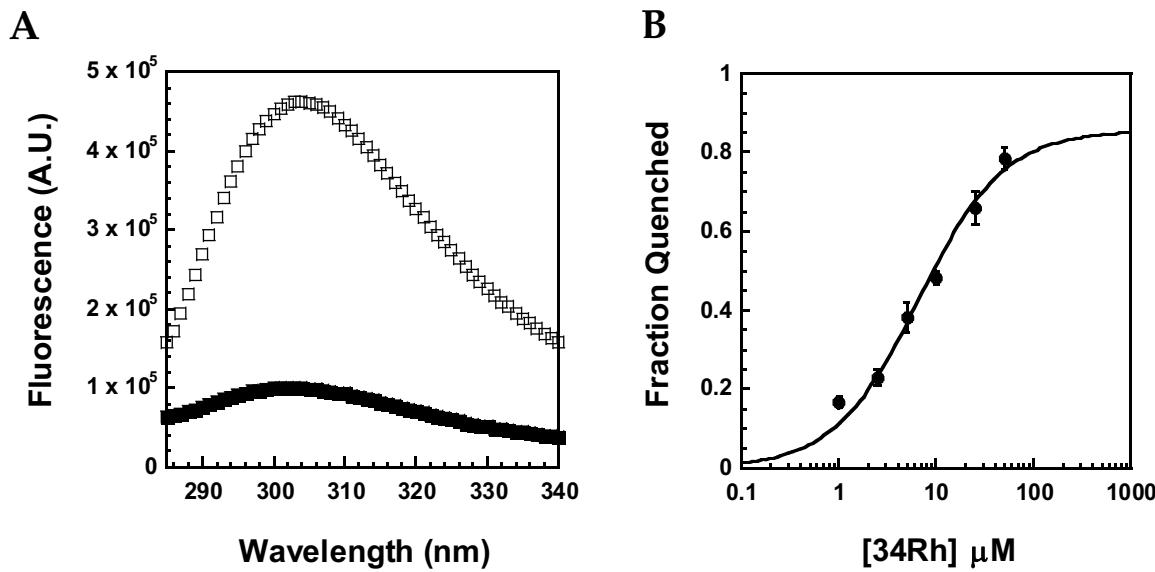

**Fig S2.** UV/Vis characterization of 34RH. (A) pH dependent deprotonation of 34RH. (B) UV/Vis absorbance of 10  $\mu$ M 34RH in 1xPBS, 5% DMSO, 25 °C, at pH 4.0 (black), pH 5.2 (dark pink), pH 6.0 (teal), and pH 7.5 (purple). (C) 34RH absorbance at 327 nm at various pH values showing a pH dependent titration fit to the Henderson-Hasselbalch equation [45].

**Fig S3.** Dynamic Light Scattering of 34RH in 1xPBS and 5% DMSO (buffer) at pH 7.4. Concentrations of 34RH are shown in the upper right corner. Concentrations below 50  $\mu$ M show no correlation function indicating that there are none to minimal nano-sized particles in the samples. At 100  $\mu$ M, a correlation was observed indicating that nano-sized particles may exist in solution. All experiments were carried out at 50  $\mu$ M and below to avoid any potential particle interference in the data.

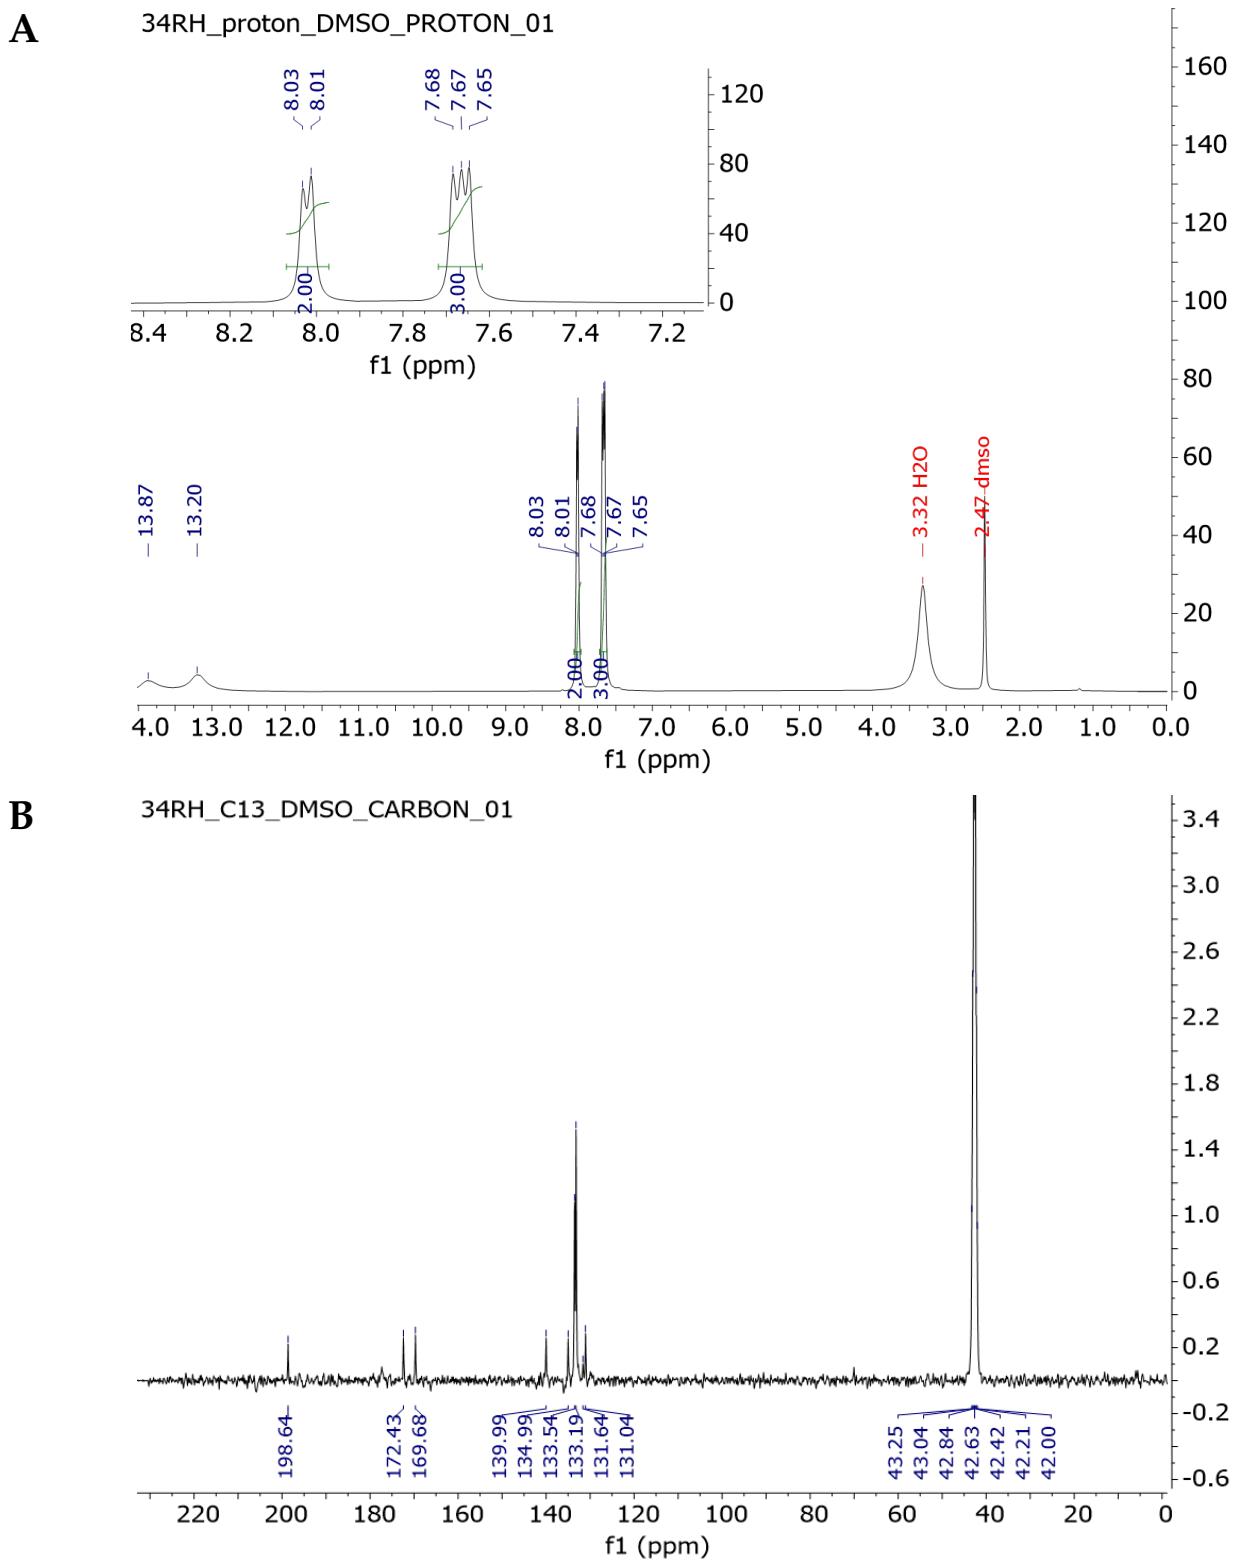

**Fig S4.** Myc<sub>353-437</sub> and 34RH interaction monitored via tyrosine fluorescence quenching and free fluorescence spectra of Myc<sub>353-437</sub> and 34RH. (A) Inner filter corrected fluorescence emission spectra of 1  $\mu$ M Myc<sub>353-437</sub> (open circles) and 1  $\mu$ M Myc<sub>353-437</sub> with various concentrations of 34RH in 1xPBS, 5% DMSO at 25 °C, pH 7.4. Concentrations of 34RH (in micromolar) are shown in the upper right corner. (B) Comparison of inner filter corrected emission spectra of 1  $\mu$ M Myc<sub>353-437</sub> (open circles) and 50  $\mu$ M 34RH without Myc (closed circles) demonstrating no fluorescence contribution from 34RH in this wavelength range.

**Fig S5.** Equimolar Myc<sub>353-437</sub> and 34RH interaction monitored via tyrosine fluorescence quenching. **(A)** 50  $\mu\text{M}$  Myc<sub>353-437</sub> in the presence (filled black squares) and absence (open black squares) equimolar 34RH in 1x PBS at 25 °C, pH 7.4. **(B)** Equilibrium quenching of an equimolar titration of Myc<sub>353-437</sub> and 34RH fit to a 1:1 binding model,  $K_D$  of  $5.9 \pm 0.8 \mu\text{M}$ . Error bars represent the standard error of three independent trials. Representative fluorescence signals were inner filter corrected to account for any fluorescence suppression due the absorbance of protein and 34RH [46]. The quenching data was fitted to a binding model shown below described in Dobrev et al.

$$\text{Fraction Quenched} = Q_{\max} \times \frac{2 + \frac{K_D}{[C]_{\text{tot}}} \sqrt{\left(-2 - \frac{K_D}{[C]_{\text{tot}}}\right)^2 - 4}}{2}$$

Here,  $Q_{\max}$  is the fraction quenched for the formation of the complete complex between Myc<sub>353-437</sub> and 34RH.  $[C]_{\text{tot}}$  is the total concentration of Myc<sub>353-437</sub> or 34RH and  $K_D$  the dissociation constant. [46,49]

**Fig S6.** NMR characterization of 34RH **A)** 1H NMR of 34RH in DMSO-d<sub>6</sub>. **B)** 13C NMR of 34RH in DMSO-d<sub>6</sub>.
