**Abstract:** The sensor signal of tin disulfide (SnS<sub>2</sub>), a two-dimensional (2D) group-IV dichalcogenide, deposited as a film on a conductometric transducer is investigated at 130 °C. The focus is on the detection of the total NO<sub>x</sub> concentration. Therefore, the sensor response to NO and NO<sub>2</sub> at ppm- and sub-ppm level at low operating temperature is determined. The results show that the sensing device provides a high sensor signal to NO and NO<sub>2</sub> even at concentrations of only 390 ppb NO<sub>x</sub>. Both nitrous components, NO and NO<sub>2</sub>, yield the same signal, which offers the opportunity to sense the total concentration of NO<sub>x</sub>.

**Keywords:** 2-dimensional SnS<sub>2</sub>; conductometric sensor; total NO<sub>x</sub> sensing; sub-ppm NO<sub>x</sub>; low temperature

## 1. Introduction

NO<sub>x</sub> sensing at low temperatures is still a difficult task, especially for air-quality monitoring in stationary or transportable air quality monitoring devices [1]. In the past years, strict emission and immission limits for NO<sub>x</sub> have been set up, for instance by the EU immission legislation Directive 2008. Currently, the emissions of NO<sub>x</sub> by traffic in urban regions are a widely discussed topic since they exceed the regulatory limits. To enforce the limits, the detection of low NO<sub>x</sub> concentrations at ppm- and sub-ppm level is required. Reliable and long-term stable sensing devices for the lowest NO<sub>x</sub> concentrations are necessary to meet the strict requirements of, for instance, the European legislation, with regard to quality of the data especially in real-time air quality monitoring [2]. In literature, various NO<sub>x</sub> gas sensing technologies are discussed [1,3–5]. The sensors have to be accurate, selective, long-term stable, and should have low NO<sub>x</sub> detection limits. Especially for air-quality monitoring, the sensors for low-temperature NO<sub>x</sub> sensing with a low power consumption are beneficial [1,2].

In this work a new material class based on 2D transition metal dichalcogenides (TMD) is discussed as sensing materials for NO<sub>x</sub> sensors [6,7]. Due to the special structure of SnS<sub>2</sub>, the charge transfer between *physisorbed* NO<sub>2</sub> gas molecules and the 2D SnS<sub>2</sub> material allows for NO<sub>2</sub> sensing with high NO<sub>2</sub> sensitivity and selectivity at low operating temperatures. In [6], the NO<sub>2</sub> sensor response of SnS<sub>2</sub> is described at 120 °C. In the present work, tin disulfide (SnS<sub>2</sub>) flakes are investigated as functional materials for NO<sub>x</sub> sensing at 130 °C with focus on the NO sensing performance of SnS<sub>2</sub>.

## 2. Materials and Methods

The transducer composed of an alumina substrate with a screen-printed interdigitated-electrode (IDE) structure (Au-IDE: 100  $\mu\text{m}$ /100  $\mu\text{m}$ ). The sensitive film of 2D  $\text{SnS}_2$  was synthesized by a wet chemical route and drop-casted on the IDE-structure [6]. The structure and morphology of the  $\text{SnS}_2$  film was analyzed by scanning electron microscopy (SEM) and transmission electron microscopy (TEM).

The sensor response, the complex impedance  $|Z|$  of the  $\text{SnS}_2$ -film, was determined at 130  $^{\circ}\text{C}$  in a synthetic gas test bench. As base gas, synthetic air with 2 vol.% water was used and  $\text{NO}$  and  $\text{NO}_2$  were added in a concentration range between 390 ppb and 2 ppm. The added  $\text{NO}_x$  concentration was analyzed downstream the sensing device by a chemiluminescence detector (CLD).

## 3. Results and Discussion

The microstructure of the  $\text{SnS}_2$  film is shown in Figure 1. The SEM image (Figure 1a) of the deposited film shows  $\text{SnS}_2$  particles with a hexagonal shape which appear to from flake like structures. This is proven by the TEM image (Figure 1b). The shape of the particle is a hexagonal plate, with an average diameter of 100 nm and a thickness of less than 10 nm. This planar 2-dimensional flake structure was selected due to its very high active surface area resulting in a high adsorption capability for physisorbed  $\text{NO}_x$  molecules.

**Figure 1.** (a) SEM image of  $\text{SnS}_2$  particles; (b) TEM image of  $\text{SnS}_2$  particles.

Initial impedance spectra of a  $\text{SnS}_2$  sensor, shown in Figure 2 in the form of Nyquist-plots (frequency between 1 MHz and 1 Hz, root-mean-square value of the amplitude 200 mV, temperature 130  $^{\circ}\text{C}$ ), present a semi-circular behavior with a high sensor signal when exposed to 390 ppb  $\text{NO}_x$ . The sensor signal in synthetic air is very stable (shown are two measurement curves). The complex impedance increases strongly in presence of  $\text{NO}_x$ , even at a  $\text{NO}_x$  concentration in the sub-ppm range.

As stated in [6] for  $\text{NO}_2$  exposure, the strong resistance increase can be explained by the effect that the adsorbed  $\text{NO}_2$  gas molecules act as electron acceptors. Charge is transferred from the  $\text{SnS}_2$  flakes to the adsorbed  $\text{NO}_2$  and the  $\text{SnS}_2$  flakes deplete with charge carriers. The reduced number of free electrons leads to the increasing resistance.

For further measurements, we selected a constant frequency of 1 Hz. The sensor was exposed to varying  $\text{NO}$  and  $\text{NO}_2$  concentration steps, and the resulting  $|Z|$  is presented in Figures 3 and 4. The impedance of the  $\text{SnS}_2$  sensor is around 600  $\text{M}\Omega$  in synthetic air, and increases when exposed to 1 ppm  $\text{NO}$  or  $\text{NO}_2$  to 2.2  $\text{G}\Omega$  with the same sensor signal for  $\text{NO}$  and  $\text{NO}_2$ . The oscillating of the sensor signal is due to temperature fluctuations of the furnace (around 10  $^{\circ}\text{C}$ ). The response time is quite good, but the signal recovery is relatively slow. The sensor seems to be a total  $\text{NO}_x$  sensing device.

**Figure 2.** Impedance spectra of a SnS<sub>2</sub> sensor at 130 °C in synthetic air and with 390 ppb NO<sub>x</sub> in the Nyquist-plot representation; spectra determined with  $U_{eff}$  = 200 mV and between 1 Hz and 10 MHz.

**Figure 3.** Complex impedance  $|Z|$  signal of the SnS<sub>2</sub> sensor determined at  $f$  = 1 Hz at 130 °C during NO<sub>x</sub> exposure to 1 ppm, 2 ppm and 0.5 ppm NO res. NO<sub>2</sub>.

**Figure 4.** Complex impedance  $|Z|$  of the SnS<sub>2</sub> sensor determined at  $f$  = 1 Hz at 130 °C during NO<sub>x</sub> exposure and the added NO<sub>x</sub> concentration analyzed by CLD downstream the sensor device.

To investigate this more in detail, Figure 4 includes the NO and NO<sub>2</sub> concentrations determined by a CLD gas analyzer. Comparing the first two NO<sub>x</sub> peaks, almost the same sensor response is visible for 5 ppm total NO<sub>x</sub> (5 ppm NO<sub>2</sub> res. 4 ppm NO with 1 ppm NO<sub>2</sub>). A huge sensor signal can be determined even for NO<sub>x</sub> concentrations below 1 ppm.

#### 4. Conclusions

The SnS<sub>2</sub> sensors show a huge NO<sub>x</sub> gas response even for low concentrations that needs to be investigated with respect to the behavior as a total NO<sub>x</sub> sensor. The developed sensing device provides high impedance values. The impedance changes strongly when exposed to low concentrations of NO or NO<sub>2</sub> and the sensor seems to be suitable for sub-ppm level NO<sub>x</sub> detection. The dependence of the resistance on the thickness of the SnS<sub>2</sub> film is an interesting task for further investigations. Additionally, the concentration dependent sensor response has to be analyzed and the response and the recovery time need to be improved.
