Deadline for manuscript submissions:

closed (20 December 2022)

Message from the Guest Editors

Electrocatalytic water splitting has now been accepted as one of the large-scale indirect mediums of energy storage in the form of chemical fuels such as H_2 and O_2 .

Most researchers focus on non-noble nanostructured materials with distinct grain boundary and high surface area to fulfill the need of efficient water oxidation electrocatalysts. Recently, non-precious electrocatalysts including metal hydroxides, layered double hydroxides, phosphides, chalcogenides, and high-entropy alloys have been the trending materials.

Therefore, this Special Issue(SI) focuses on the state of the art in “High-Performance Water Oxidation Electrocatalysts: Synthesis and Application”. Research outcomes focusing on water oxidation electrocatalyst synthesis, fundamental approaches used to understand the active sites, new mechanisms of exploration, and advanced in-situ/ex-situ characterizations, including applications in technological- and industrial-scale development of water oxidation in the field of water splitting are of prime importance to this SI.
