Message from the Guest Editor

Dear Colleagues,

Invasive insect herbivores tend to have populations that are more abundant and damaging in the area that they successfully invade. Once established in the new area, invasive insect herbivores exert strong negative impacts on urban landscapes, agroecosystems, and native habitats, which often have negative economic and environmental outcomes. Key issues related to managing invasive insects include knowledge gaps regarding the development of risk assessments for species before and after they arrive in a new area, proactive management solutions, early detection and rapid response programs, frugality and pragmatism, and the need for industry and consumer cooperation and education.

This Special Issue brings together a diverse group of key experts, addressing some of these important questions related to invasive insect species ecology and control. Submissions could be reviews, short communications, concept papers, or original research articles that present new data and analyses.
