Message from the Guest Editors

Dear Colleagues,

High throughput proteomic analysis provides powerful tools for the discovery of novel biomarkers, which could be used in the diagnosis and/or prognosis of diseases. Consequently, protein microarrays have been widely used for profiling biomarkers related with disease development and progression. The advantage of microarrays is that they allow for high throughput screening of large numbers of biomarkers, using minute amount of samples. This special issue will summarize the utilization of antibody microarrays and their implication in clinical settings. The focus will be both on recent technology developments in this field as well as the usefulness of this technique to demonstrate clinical utility and unmet medical needs, such as early diagnosis, patient stratification and evidence therapy selection.
