

Joint Special Issue

The Immunosocial Approach to Emerging and Re-emerging Microbial Infections

Message from the Guest Editor

The immunosocial approach to emerging and re-emerging microbial infections represents an innovative framework that integrates immunological science with social factors to develop comprehensive strategies for managing disease outbreaks. This approach acknowledges that the human immune response to infections is not solely influenced by biological factors but is also significantly shaped by social determinants such as community behaviors, socio-economic conditions, and public health infrastructure. By bridging the gap between biological and social sciences, the immunosocial approach aims to create more effective and sustainable solutions for disease control and prevention. In calling for a Special Issue on The Immunosocial Approach to Emerging and Re-emerging Microbial Infections, we aim to highlight and promote research that explores the intersection of immunology and social sciences. This interdisciplinary perspective is crucial for developing innovative and effective strategies to combat microbial infections and enhance global public health resilience.
