Deadline for manuscript  
submissions:

**closed (25 March 2022)**

### Message from the Guest Editors

Cirrhosis is common, and the twelfth-leading cause of death worldwide. The major complications of cirrhosis include varices, ascites, hepatic encephalopathy (HE), hepatopulmonary hypertension, hepatocellular carcinoma, hepatorenal syndrome, spontaneous bacterial peritonitis, and coagulation disorders. Patients with cirrhosis require constant monitoring both in and outside the hospital. Internists and nurses play an important role in the management and prevention of complications of liver cirrhosis and improvement in connection between clinicians and families. Nursing care includes education about the complications of cirrhosis, prevention, and early detection through specific symptoms.

This Special Issue aims to present research articles as well as critical reviews that address challenges to see and understand the role of internists and nursing care in the treatment of patients with liver cirrhosis.
