Deadline for manuscript
submissions:

20 March 2025

Message from the Guest Editor

Machine learning and data-driven algorithms are promising approaches in analysing the dynamic behaviour of a mechanical system. These algorithms have the ability to automatically generate a model using data from past experiences; the number of applications is extensive and includes self-driving cars, high-frequency trading, house price estimation, search engines, bioinformatics, chemistry, and material science, for which large amounts of data are available.

This Special Issue aims to collect the latest research findings in the field and invites the submission of articles related (but not limited) to the following topics:

- Surrogate machine learning approaches for the stress analysis of vibrating systems;
- Data-driven approaches for structural health monitoring;
- Machine learning approaches for sensor optimization in vibration analysis;
- Data-driven real-time stress predictions;
- Machine learning applications in relation to finite element analysis for vibrating systems;
- Uncertainty quantification in the stress analysis of machine learning modelling;
- Data-driven modal analysis;
- Physics-informed machine learning approaches for vibrating systems.
